Lecture 1 (11-01-2021)

11 January 2021 09:34

Recap of Regular Languages

Different formalisms surprisingly describe the same class of languages. Regular expressions, DFA, NFA, MSO logic.

Notation and Setup (for the rest of course)

Fix a finite alphabet Σ .

A (finite) word over Σ is a finite sequence $a_0 a_1 \dots a_n$ of elements of Σ . $u, v, w \dots$ are used for words.
 $w = a_0 a_1 \dots a_n$ where each $a_i \in \Sigma$.

The empty sequence corresponds to the unique word of length 0 and is denoted by ϵ , the empty word.

Σ^* = the set of all finite words over Σ . ($\epsilon \in \Sigma^*$)

$\Sigma^+ = \Sigma^* \setminus \{\epsilon\}$ = the set of all non-empty words over Σ .

CONGATENATION of words:

$$\cdot : \Sigma^* \times \Sigma^* \rightarrow \Sigma^* \\ (u, v) \mapsto u \cdot v$$

defined in the usual manner.

→ The \cdot operation on Σ^* is associative.

That is, $\forall u, v, w \in \Sigma^* : (u \cdot v) \cdot w = u \cdot (v \cdot w)$.

→ ϵ acts as an identity for \cdot .

This is an example of a monoid $(X, *)$

$$\forall w \in \Sigma^*: f \cdot w = w \cdot f = w.$$

(Another example of monoid: $(\mathbb{N}, +)$
 $\mathbb{N} = \{0, 1, \dots\}$ in this course
 (Later we'll look at finite monoids.)

$$l: \Sigma^* \rightarrow \mathbb{N}$$

$$u \mapsto \text{length of } u = l(u)$$

Note $l(u \cdot w) = l(u) + l(w)$
 $l(\epsilon) = l(0)$

Thus, l is a monoid morphism.

Def.: A language L is simply a subset of Σ^* . (Language)

Given languages $L_1, L_2 \subset \Sigma^*$, we define

$$L_1 \cdot L_2 = \{w_1 \cdot w_2 \mid w_1 \in L_1, w_2 \in L_2\}.$$

REGULAR EXPRESSIONS (Regular expressions)

$$r \equiv \emptyset \mid \epsilon \mid a \mid r_1 + r_2 \mid r_1 \cdot r_2 \mid r^*$$

$r \rightsquigarrow L(r)$ language associated to r

$L(r)$ is defined by structural induction on r .

- $L(\emptyset) = \emptyset$
- $L(\epsilon) = \{\epsilon\}$
- $L(a) = \{a\}$ ($a \in \Sigma$)
- $L(r_1 + r_2) = L(r_1) \cup L(r_2)$
- $L(r_1 \cdot r_2) = L(r_1) \cdot L(r_2)$ (RHS defined earlier)

$$\begin{aligned} L(r^*) &= \{\epsilon\} \cup L(r) \cup L(r) \cdot L(r) \cup L(r) \cdot L(r) \cdot L(r) \cup \dots \\ &= \bigcup_{i=0}^{\infty} L^i \quad \left(L^0 = \{\epsilon\}, L^1 = L(r), L^{i+1} = L^i \cdot L \right) \end{aligned}$$

[Example. $(ab)^* = \{\epsilon, ab, abab, \dots\}$.]

Defn. A language $L \subseteq \Sigma^*$ is said to be **regular** if there exists a regular expression r such that $L(r) = L$. (Regular language)

Thm. Regular languages are closed under union, intersection, complementation, concatenation.

(As per our defⁿ using regular expressions, Union & concatenation are obvious.)

Some of the above is easier to prove under diff. formalisms. One first shows that two diff. formalisms are actually same.

Defn. (Extended reg. expressions) (Extended regular expressions)

$$r \equiv \phi \mid \epsilon \mid a \mid \underset{\epsilon}{r_1 + r_2} \mid r_1 \cdot r_2 \mid \neg r \mid r \cdot r_2 \mid r^*$$

These we can add, in view of thⁿ, w/o changing the class of languages

Q: What subclass of language will we get if we restrict ourselves to a subset of the operators?

Defn. (Star-free ^{extended} reg. expressions) Exclude the * operator.

(Star-free regular expressions)

Def: (Star-free ^{or} reg. expressions) Exclude the * operator.

(Star-free regular expressions)

Q. Which regular languages admit a star free representation?

(Non?) Example : $r = (ab)^*$

Can we rewrite this without * ?

The "extended" is important. Else, we get trivial classes.

Lecture 2 (14-01-2021)

14 January 2021 11:35

Note that $\neg \phi = \Sigma^*$
can use this freely

Observe: $a^* = \neg(\underbrace{\Sigma^* \cdot b \cdot \Sigma^*}_{\text{words containing at least } b})$

Similarly $(ab)^* \rightarrow \text{words starting with } a, \text{ ending with } b,$
 $\text{no lone active } a \text{ or } b \text{ (or } \epsilon\text{)}$

$$(ab)^* = \epsilon + [\alpha \Sigma^* b \cap \neg(\Sigma^* aa\Sigma^* + \Sigma^* bb\Sigma^*)]$$

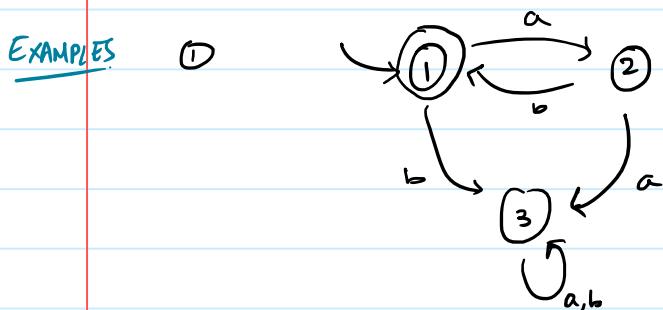

It is not even clear a priori whether the question
"Which languages have *-free expression" is even decidable.

Finite state Automata (Finite state automata)

(NFA)

$$A = (Q, \Sigma, Q_0 \subseteq Q, \Delta \subseteq Q \times \Sigma \times Q, F \subseteq Q)$$

finite set initial states transition $(q_i, a, q_j) \in \Delta$ final states

$$\begin{aligned} Q &= \{1, 2, 3\} \\ Q_0 = F &= \{1\} \\ \Sigma &= \{a, b\} \end{aligned}$$

Language accepted: $(ab)^*$

Defn Suppose $w = a_0 \dots a_n \in \Sigma^*$.

A run ρ of A on w is a sequence of states

$$\rho = q_0, \dots, q_{n+1}$$

↑ note $n+1$

such that

- $q_0 \in Q_0$
- $(q_i, a_i, q_{i+1}) \in \Delta \quad \forall i = 0, \dots, n$

The run ρ is accepting if $q_{n+1} \in F$.

(Note that a word may have no run or even multiple runs.)

The language $L(A)$ of A is defined as

$$L(A) = \{ w \in \Sigma^* : A \text{ has at least one accepting run} \}.$$

A is deterministic if $|Q_0| = 1$ and

$$\forall q \in Q, \forall a \in \Sigma, \exists! \underbrace{q' \in Q}_{\text{there exists unique}} \text{ s.t. } (q, a, q') \in \Delta.$$

→ In other words, $\Delta \subseteq (Q \times \Sigma) \times Q$ is a function

$$Q \times \Sigma \rightarrow Q.$$

The example above was actually deterministic. It is called a DFA.

Thm. [TOC] (Kleene's Theorem)

Regular expressions \equiv NFA \equiv DFA.

(That is, all three formalisms talk about the same class of language - regular languages.)

(Recap of Proof.)

Reg. Exp \in NFA

$$\begin{array}{ccc} r & \mapsto & Ar \\ \text{reg exp} & & \uparrow \text{NFA} \end{array}$$

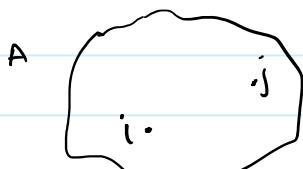

$$L(r) = L(A_r).$$

The way to do this is by induction.

- For ϵ and 'a', easy.
- $r = r_1 + r_2$. We have NFAs for r_1 and r_2 . Then, the NFA $A_r = Ar_1 \sqcup Ar_2$ works.
Allowed since non-determinism \rightarrow

- $r_1 \cdot r_2$. Use ϵ -transitions. Idea is to take union and put ϵ transitions from F of Ar_1 to Q_0 of Ar_2 . The final states are now F of Ar_2 and initial is Q_0 of Ar_1 .
- r^* . Same sort of idea as above but loop on self.

NFA \subseteq Reg. Exp.

$$Q = \{1, \dots, n\}$$

r_{ij} = a reg. exp. which captures the words which allow to go from i to j .

Then $r := \bigcup_{\substack{i \in Q_0 \\ j \in F}} r_{ij}$ works.

Thus, only need to figure out r_{ij} .

'Dynamic Programming'

Introduce a third parameter k .

r_{ij}^k = reg. expression words w which have a

- run ρ of A s.t.
- ρ starts at i
 - ρ ends at j
 - all intermediate states of ρ are in $\{1, \dots, k\}$.
(include $k = 0$)

Start building r_{ij}^k going from $k = 0$ to $k = n$.
Note that $r_{ij} = r_{ij}^n$.

$r_{ij}^0 \equiv$ start at i , end at j , no intermediate state
 \equiv all those letters which allow transition from i to j .
(if any)

$$\begin{aligned} r_{ij} &= a_1 + a_2 + \dots + a_p & (i \neq j) \\ &= a_1 + \dots + a_p + \epsilon & (i = j) \end{aligned}$$

a_1, \dots, a_p
 ϵ

$$r_{ij}^k = r_{ij}^{k-1} + r_{ik}^{k-1} \cdot (r_{kk}^{k-1})^* \cdot r_{kj}^{k-1}$$

(We build for lower k first for all (i, j))

Thus, Reg f.p. \equiv NFA.

NFA \equiv DFA. DFA \subseteq NFA is obvious.

Converse:

$$A = (Q, \Sigma, Q_0, \Delta, F).$$

The idea to get an equivalent DFA is the powerset construction.

$$B = (2^Q, \Sigma, Q_0, \delta: 2^Q \times \Sigma \rightarrow 2^Q, F')$$

Idea is to keep track of all the states that you can reach from given state.

$$\delta(x, a) = \{q \in Q : \exists q' \in X, q' \xrightarrow{a} q\}.$$

Lecture 3 (18-01-2021)

18 January 2021 09:04

Today, we see another formalism to describe regular languages. A natural way to describe a language is to give a "property" of words.

Examples:

1) Every (occurrence of an) 'a' is eventually followed by a 'b'.
 $aabbaab \checkmark$ $bababac \times$

2) There is exactly one 'a' in the word.

3) The first position is labelled 'a'.

4) There are even number of 'a's.

We need a formal language to do so.

Formal Language : Should allow us to do "Boolean" properties like "and", "or", et cetera.

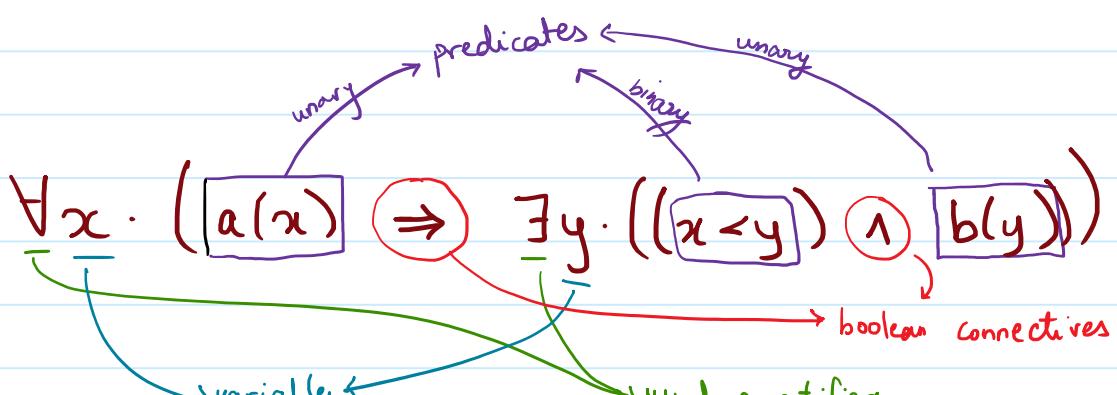

Going to use a Mathematical Logic for doing so.

First-Order Logic (over words)

(First Order Logic)

before formal defn & syntax.

An example of a formula in this logic:

variables → going to range over positions in the word
 variables → boolean connectives
 usual quantifiers → x_0, x_1, x_2, \dots

$\text{FO } [\Sigma] -$ variables :- x, y, z, \dots | range over
 x_0, x_1, x_2, \dots | positions

- predicates :-
- letter predicates
- $a \in \Sigma, a(x)$ says the letter ' a ' at position ' x ' (true/false)
- binary predicates, $y < z$
- equality $x = y$

$$\varphi \equiv a(x) \mid x < y \mid x = y \mid \varphi \vee \varphi \mid \neg \varphi \mid \exists x \cdot \varphi$$

can get $\varphi \wedge \varphi, \varphi \Rightarrow \varphi, \varphi \Leftrightarrow \varphi, \forall x \cdot \varphi$
 using these

The above was a sentence, there was no free variable.

$$\text{first}(x) \equiv \forall y \cdot [(x = y) \vee (x < y)] \quad \leftarrow \text{here } x \text{ is free}$$

Given this formula, if we wish to find truth of $\text{first}(x)$ on some word w , we need to give x .

$$w = \begin{smallmatrix} 1 & 2 & 3 & 4 & 5 \\ abaaab \end{smallmatrix}$$

$$w, x \leftarrow ? \models \text{first}(x) ?$$

if true, we write: $w, x \leftarrow 2 \models \text{first}(x)$

else : $w, x \leftarrow 2 \not\models \text{first}(x)$

Easy to see $w, x \leftarrow 2 \not\models \text{first}(x)$. Why?

We need to check if for all positions 'p' in w :

$$w, x \leftarrow ?, y \leftarrow p \models (x = y) \vee (x < y)$$

If $P=4$, then we check $(2=4) \vee (2 < 4)$

<u>false</u>	<u>true</u>
--------------	-------------

true!

However, if $P = 1$, then $(2=1) \vee (2 < 1)$

<u>false</u>	<u>false</u>
--------------	--------------

false

Then, $w, x \leftarrow 2 \not\models \text{first}(x)$. $\left(\text{We had the universal quantifier.} \right)$

Easy to see $\text{first}(x)$ is true iff x is the first position.

Now, we can use $\text{first}(x)$.

Defn.: A sentence is a formula without free variables.

(Sentence)

Example • $\varphi = \exists x \cdot [\text{first}(x) \wedge b(x)]$ is a sentence.
Now makes sense to ask " $\text{abaab} \models \varphi$ " without any assignment. ($\text{abaab} \not\models \varphi$)

the first position is labelled 'b'

• Exactly one 'a':

$$\{\forall x \forall y [(a(x) \wedge a(y)) \Rightarrow x=y]\} \wedge \{\exists x \cdot a(x)\}$$

• $(ab)^*$ ← can you write a first order sentence which gives this regex?

$$\{\forall x [\text{first}(x) \Rightarrow a(x)]\} \wedge \{\forall x [a(x) \Rightarrow \exists y \cdot (s(x,y) \wedge b(y))]\}$$

$s(x,y) = (x < y) \wedge \forall z (z < x \vee y < z)$.

• There are even numbers of 'a's → is regular, can

come up with an automata

The other three examples were also regular. (Also expressible by FOL)
However, FOL cannot describe this logic!
But every language definable by FOL WILL be regular!

FOL → FOL-definable languages

REG → collection of reg. languages

$\boxed{\text{FO} \subsetneq \text{REG}}$

We shall extend FOL to MSO → Monadic Second Order Logic.

Lecture 4 (19-01-2021)

19 January 2021 10:35

MSO (Monadic Second Order Logic - Over Words)

(MSO Monadic Second Order Logic)

Here, we have position variables : $x, y, z, \dots, x_0, x_1, \dots$

Set of position variables : $X, Y, Z, \dots, X_0, X_1, \dots$

Predicates : $a(x) - a \in \Sigma$ (Unary)

$x = y$ (Binary)

$S(x, y)$ - successor : 'y' is a successor of 'x'
(membership predicate) $X(x) - 'x' \text{ belongs to } X [x \in X]$

$$\varphi = a(x) | x = y | S(x, y) | X(x) | \varphi \vee \psi | \neg \varphi | \exists x. \varphi | \exists X. \varphi$$

Eg of formula: $\forall X \exists x. x \in X$

Convention (notation) : $\varphi(x_1, \dots, x_m, X_1, \dots, X_n)$ - φ is an MSO formula
 x_1, \dots, x_m are free pos. var
 X_1, \dots, X_n ——— set var.

Semantics (Semantics) "truth" / "models" relation.

$w \in \Sigma^*$ - a finite word

p_1, \dots, p_m - m positions in w ,

Q_1, \dots, Q_n - n sets of positions in w .

$w, p_1, \dots, p_m, Q_1, \dots, Q_n \models \varphi$

(p_1, \dots, p_m are "concrete" positions)
(Q_1, \dots, Q_n ——— sets)

want to define when this happens.
($x \leftarrow p_1, \dots, x \leftarrow p_m$, $x \leftarrow Q_1, \dots, x \leftarrow Q_n$ is understood)

Defined by structural induction on φ

- $w, p_i \models a(x_i)$ if the letter in w at position p_i is a a
 - $w, p_i, Q_i \models x_i(a)$ if $p_i \in Q_i$
 - $w, p_1, \dots, p_m, Q_1, \dots, Q_n \models \psi(x_1, \dots, x_m, x_1, \dots, x_n) = \psi_1 \vee \psi_2$
iff $w, p_1, \dots, p_m, Q_1, \dots, Q_n \models \psi_1$ or $w, \dots \models \psi_2$
 - $w, \dots \models \neg \psi$ iff $w, \dots \not\models \psi$
 - $w, p_1, \dots, p_m, Q_1, \dots, Q_N \models \psi(x_1, \dots, x_m, x_1, \dots, x_N) = \exists x_{m+1} \psi'(x_1, \dots, x_m, x_{m+1}, \dots, x_n)$
iff there exists a position p_{m+1} in w s.t.
 $w, p_1, \dots, p_m, p_{m+1}, Q_1, \dots, Q_N \models \psi'(x_1, \dots, x_{m+1}, x_1, \dots, x_n)$.

ple

$$\psi \equiv \forall x \exists x \cdot x(x) \wedge a(x) \equiv \forall x \cdot \psi'(x)$$

!!!

$$\exists x \cdot X(x) \wedge a(x)$$

Example

$$\varphi \equiv \forall x \cdot \exists x \cdot X(x) \wedge a(x) \quad \equiv \quad \forall x \cdot \varphi'(x)$$

" "
 $\exists x \cdot X(x) \wedge a(x)$

$a \models \varphi$; $a \models \varphi$ if for all subsets Q of positions in a ,
 $a_Q, Q \models \varphi'(x)$

Thus, $aa \neq 0$.

FO: $a(x), \quad x < y, \quad x = y, \quad \text{boolean}, \quad \exists x, \quad \forall x$

MSO: $a(x), \quad S(x, y), \quad \exists u \quad \underline{\hspace{1cm}}, \quad \exists x, \forall x$

Is $F_0 \subseteq MSO$? If we had ' \leq ' in MSO, would be obvious.

As it turns out, we can write '`<`' in MSO, since we have set variables.

Lecture 5 (21-01-2021)

21 January 2021 11:36

$$\text{MSO } [S] : \varphi \equiv a(x) \mid x = y \mid \leq(x, y) \mid x(x) \mid \varphi \vee \varphi \mid \neg \varphi \mid \exists x. \varphi \mid \exists x. \varphi$$

$$\text{FO } [<] : \varphi \equiv a(x) \mid x = y \mid x < y \mid \varphi \vee \varphi \mid \neg \varphi \mid \exists x. \varphi$$

$$\text{FO } [S] : \varphi \equiv a(x) \mid x = y \mid \leq(x, y) \mid \dots$$

(Obvious semantics for all three above.)

Q. How do $\text{FO} [<]$ and $\text{FO} [S]$ compare?

Can a property in one logic be written in the other?

If ' S ' can be expressed in $\text{FO} [<]$, then $\text{FO} [S] \subseteq \text{FO} [<]$.

$$S(x, y) \equiv (x < y) \wedge \neg(\exists z ((x < z) \wedge (z < y)))$$

Can ' $<$ ' be expressed in $\text{FO} [S]$?

No.

Thus, $\text{FO} [S] \subsetneq \text{FO} [<]$.

$\text{FO} [S] \subseteq \text{MSO} [S]$. Clear.

However, we also have $\text{FO} [<] \subseteq \text{MSO} [S]$.

Suffices to show ' $<$ ' can be expressed in $\text{MSO} [S]$

$$x < y \equiv (\neg(x = y)) \wedge (\forall x [(x(x) \wedge S(x)) \Rightarrow x(y)])$$

$$\text{succ}(x) = \forall z \forall w \left\{ [x(z) \wedge s(z, w)] \Rightarrow x(w) \right\}$$

succesor closed

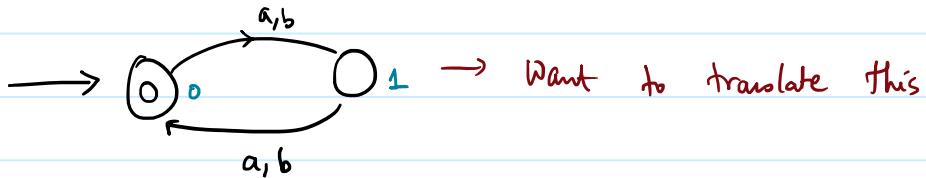

iff x is not equal to y and every subset which contains x and closed under successor also contains y .

$$\text{Thus, } FOL[S] \subsetneq FO[<] \subseteq MSO[S] = MSO[S, <].$$

In fact,

$$FO[<] \subsetneq MSO[S].$$

"Words of even length" can be expressed in $MSO[S]$
but not in $FO[<]$. (Proof. Later. ②)

Want to translate this

$\vdash w$ has even length $\Leftrightarrow \exists X$ a subset X of positions in w s.t.

- first(x) \leftarrow 1) X contains the first position
- note this used $'x'$ but can use that now 2) X contains every alternate position
- 3) X does not contain the last position

$$\exists X \left[\left[\exists x. [\text{first}(x) \wedge x \in X] \right] \wedge \left[\forall y \forall z. [s(y, z) \Rightarrow [x(y) \Leftrightarrow \neg x(z)]] \right] \wedge \left[\exists x. [\text{last}(x) \wedge \neg x(x)] \right] \right]$$

[non empty words]

Note $\epsilon \models \forall x. \neg(x = x)$

$$\left[\begin{array}{l} \text{Recall: } w = \epsilon \nmid \exists x. \varphi \\ w = \epsilon \models \forall x. \varphi \end{array} \right]$$

\hookrightarrow can or with this

For convenience, we may switch to Σ^* and forget about ϵ since we can always take care of it separately.

since we can always take care of it separately.

Defⁿ. Let $L \subseteq \Sigma^*$. We say L is MSO[s]-definable if \exists a MSO[s] sentence φ s.t.

$$L = \{w \mid w \models \varphi\} \equiv L(\varphi).$$

(We will drop the "[s]" and just say "MSO".)

Thm. [Büchi- Elgot] Let $L \subseteq \Sigma^*$.
 L is regular iff L is MSO-definable.

More importantly, the proof (transitions b/w automata & MSO) is effective.

↳ Can write a program which does this conversion.

Lecture 6 (25-01-2021)

25 January 2021 02:16

Thm. (Büchi-Egert Theorem)

L is regular iff it is MSO-definable.

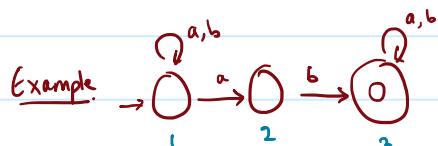

Proof. (\Rightarrow) Suppose $A = (Q, \Sigma, q_0, \Delta \subseteq Q \times \Sigma \times Q, F)$ can assume unique start state

be an NFA such that $L(A) = L$.

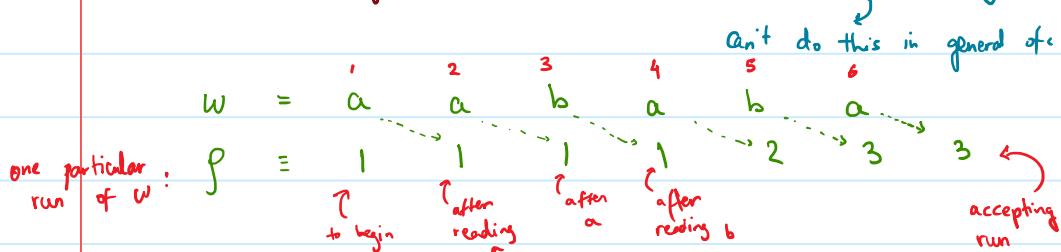

We show \exists an MSO sentence φ_A s.t.

$\forall w \in \Sigma^*$, $w \models \varphi_A$ iff $w \in L(A) = L$.

that is, ↓ an accepting run of A on w

$$\varphi_A = \exists x \exists y . [S(x, y) \wedge a(x) \wedge b(y)] \quad \text{(after inspecting and explicitly finding)}$$

Idea is to capture the state sequence using set var.

$X_1 = \{1, 2, 3, 4\}$ ← set of positions that run ρ was in state 1

$X_2 = \{5\}$

$X_3 = \{6\}$ (ignoring the final state for now)

$$A = (Q, \Sigma, q_0, \Delta, F)$$

$$w = a_0 a_1 a_2 \dots a_n$$

$$\rho = q_0 q_1 q_2 \dots q_n q_{n+1}$$

We encode this ρ by a set of $\{X_q\}_{q \in Q}$

X_q = the positions in ρ when it is in state q

These sets $\{X_q\}_{q \in Q}$ have the following properties

- (1) $\{X_q\}_{q \in Q}$ is a partition of positions. (Some X_q may be empty, though.)
- (2) The first position belongs to X_{q_0} .
- (3) If two consecutive positions $p < p'$ are in the sets X_q and $X_{q'}$, respectively, then the letter at position p allows to move from q to q' .

(1) - (3) are saying that it is a valid run

Accepting run

- (4) If the last position is in X_{q_f} , then there is a transition from q_f on the last letter to a final state.

$$Q = \{0, 1, \dots, m\}$$

$\nwarrow q_f$

To make φ_A s.t. $w \models \varphi_A$ iff A accepts w

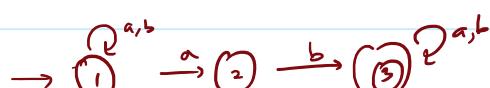

$$\begin{aligned} \varphi_A \equiv \exists x_0 \exists x_1 \dots \exists x_m : & \left[\begin{array}{l} \{\text{partition}(x_0, x_1, \dots, x_m)\} \wedge \\ \{\text{first-position-is-in-}x_0\} \wedge \end{array} \right. \\ & \left. \left\{ \forall x \forall y [S(x, y) \Rightarrow \bigvee_{(q, a, q') \in \Delta} (X_q(x) \wedge X_{q'}(y) \wedge a(x))] \right\} \wedge \right. \\ & \left. \left\{ \exists x [\text{last}(x) \wedge \bigvee_{\substack{(q, a, q') \in \Delta \\ \text{and } q' \in F}} (X_q(x) \wedge a(x))] \right\} \right] \end{aligned}$$

where

$$\text{partition}(x_0, \dots, x_m) \equiv \forall x \left[\left(\bigvee_{i=0}^m X_i(x) \right) \wedge \left(\bigwedge_{i \neq j} \neg (X_i(x) \wedge X_j(x)) \right) \right]$$

$$\text{first-position-is-in-}x_0 \equiv \exists x [\text{first}(x) \wedge X_0(x)]$$

For example:

$$\varphi_A \equiv \exists x_1 \exists x_2 \exists x_3 : \left\{ \begin{array}{l} \{\text{partition}(x_1, x_2, x_3)\} \wedge \\ \{\text{first}(x_1) \wedge X_1(x_1)\} \wedge \\ \{x_1 \xrightarrow{a} x_2\} \wedge \\ \{x_2 \xrightarrow{b} x_3\} \wedge \\ \{X_3(x_3) \wedge (a, b)\} \end{array} \right.$$

$$\varphi_1 \equiv \exists X_1 \exists X_2 \exists X_3 : \{ \text{partition } (x_1, x_2, x_3) \} \wedge$$

{first in -x_i} \wedge

$$\left\{ \forall x \forall y : S(x, y) \Rightarrow \left[\begin{array}{l} (x_1(x) \wedge a(x) \wedge x_1(y)) \vee \\ (x_1(x) \wedge b(x) \wedge x_1(y)) \vee \\ (x_1(x) \wedge a(x) \wedge x_2(y)) \vee \\ (x_2(x) \wedge b(x) \wedge x_2(y)) \vee \\ (x_2(x) \wedge a(x) \wedge x_3(y)) \vee \\ (x_3(x) \wedge a(x) \wedge x_3(y)) \end{array} \right] \right\} \wedge$$

$$\left\{ \exists x \text{ last}(x) \wedge \left[\begin{array}{l} (x_2(x) \wedge b(x)) \vee \\ (x_3(x) \wedge a(x)) \vee \\ (x_3(x) \wedge b(x)) \end{array} \right] \right\}$$

Can add the empty word separately if required!

The above is a nice construction since the "length of formula" is roughly that of the automaton.

Lecture 7 (28-01-2021)

28 January 2021 11:30

Last time, we proved one direction of the Büchi-Egert Theorem.
Namely, if L is regular, then L is MSO-definable.
Now, we see (\Leftarrow).

Proof: MSO₀-logic — eliminate position variables
using 'singleton' set variables

atomic predicates:
 $\text{Sing}(x)$ — " x " is a singleton set
 $a(x) \rightsquigarrow a(x)$ — every position in " x " is "a"
 $S(x,y) \rightsquigarrow S(x,y)$ — x and y are singletons and
the correxp. positions are related by S
 $x = y \quad \} \rightsquigarrow (x \subseteq y)$ — x is a subset of y
 $x(n) \quad \} \rightsquigarrow \text{subset}(x,y)$

Claim: MSO and MSO₀ have the same expressive power. \square

Goal: MSO₀ sentence to automata translation.

The above is done by structural induction on the formula.

$\Psi(x_1, \dots, x_n)$ — MSO₀-formula with n free variables
(only need to look at set variables)

$w, Q_1, \dots, Q_n \models \Psi(x_1, \dots, x_n)$
encode this information by a word over an extended alphabet

Example:

$$w = \begin{matrix} 1 & 2 & 3 & 4 & 5 & 6 \\ a & b & a & a & b & a \end{matrix} \quad X_1 = \{1, 3, 4\} \quad X_2 = \{3, 4, 5\}$$

Construct w' = $\begin{pmatrix} a \\ 1 \\ 0 \end{pmatrix} \begin{pmatrix} b \\ 0 \\ 0 \end{pmatrix} \begin{pmatrix} a \\ 1 \\ 1 \end{pmatrix} \begin{pmatrix} a \\ 1 \\ 1 \end{pmatrix} \begin{pmatrix} b \\ 0 \\ 0 \end{pmatrix} \begin{pmatrix} a \\ 0 \\ 1 \end{pmatrix}$

We have a new alphabet $\Sigma^* = \Sigma \times \{0, 1\}^n$
 $\varphi(x_1, \dots, x_n) \rightsquigarrow A_\varphi \leftarrow \text{construct automata s.t.}$

$\forall w' \in \Sigma^*, w' \models \varphi \text{ iff } A_\varphi \text{ accepts } w'$

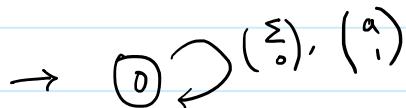

Let us now construct A_φ by structural induction.

Base cases:

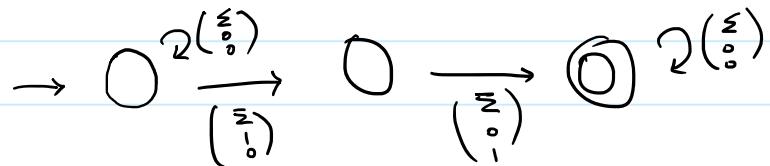

$\varphi(x_1) = S(x_1) \rightsquigarrow A_\varphi \text{ over } \Sigma \times \{0, 1\}$

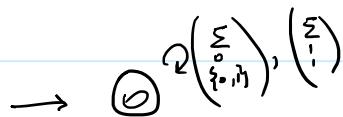

$\varphi(x_1) = a(x_1) \rightsquigarrow A_\varphi \text{ over } \Sigma \times \{0, 1\}$

$\varphi(x_1, x_2) = S(x_1, x_2) \rightsquigarrow A_\varphi \text{ over } \Sigma \times \{0, 1\} \times \{0, 1\}$

$\varphi(x_1, x_2) = x_1 \leq x_2 \rightsquigarrow \Sigma \times \{0, 1\}^2$

• $\varphi(x_1, \dots, x_n) = \varphi_1(x_1, \dots, x_n) \vee \varphi_2(x_1, \dots, x_n)$

can assume free variables

induction

• We have A_{φ_1} and A_{φ_2} . We know how to construct union of automata. Thus, we are done.

- $\varphi \equiv \neg \psi$. Have A_ψ , can construct automata for $\neg \psi$.
(toggle the final states, if PFA.)
- $\varphi(x_1, \dots, x_n) = \exists x_{n+1} \varphi'(x_1, \dots, x_{n+1})$

Lecture 8 (01-02-2021)

01 February 2021 09:25

φ - MSO₀ formula

$\varphi \rightsquigarrow A\varphi$ by structural induction on φ

$$\varphi(x_1, \dots, x_n) = \exists x_{n+1} \varphi'(x_1, \dots, x_n, x_{n+1})$$

By induction, we have $A\varphi'$ over $\sum \times \{0, 1\}^{n+1}$ such that
 $\forall w \in (\sum \times \{0, 1\}^{n+1})^*$, $w \models \varphi' \Leftrightarrow A\varphi' \text{ accepts } w$

Goal: to construct $A\varphi$ corresponding to φ over $\sum \times \{0, 1\}^n$.

$$\forall w \in (\sum \times \{0, 1\}^n)^*, w \models \varphi$$

iff \exists a subset of positions Q of pos. in w s.t.

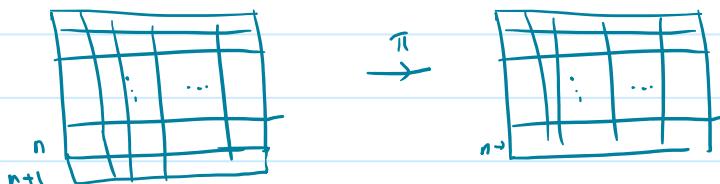

$$w, x_{n+1} \leftarrow Q \models \varphi$$

Consider the projection map $\pi: \sum \times \{0, 1\}^{n+1} \rightarrow \sum \times \{0, 1\}^n$
 $(a, b_1, \dots, b_{n+1}) \mapsto (a, b_1, \dots, b_n)$.

This extends to a map (which we call π again) as
(homomorphism)

$$\pi: (\sum \times \{0, 1\}^{n+1})^* \rightarrow (\sum \times \{0, 1\}^n)^*$$

which acts pointwise.

Thus, $w \models \varphi$ iff $\exists w' \in (\sum \times \{0, 1\}^{n+1})^*$ s.t. $\pi(w') = w$
and $w' \models \varphi'$.

$$\text{Note } L(\varphi') \subseteq (\sum \times \{0, 1\}^{n+1})^*, L(\varphi) \subseteq (\sum \times \{0, 1\}^n)^*$$

By our above discussion, we have:

$$\pi(L(\varphi')) = L(\varphi).$$

Note that $L(\varphi')$ regular $\Rightarrow \pi(L(\varphi'))$ is regular
since π is a homomorphism.

$A_{\varphi'} = (Q, \Sigma \times \{0, 1\}^{n+1}, \delta', F) \leftarrow \text{given}$

$A_{\varphi} = (Q, \Sigma \times \{0, 1\}^n, \Delta, F) \leftarrow \text{construct, where}$

$\Delta: q \xrightarrow{(a, b_1, \dots, b_n)} q' \quad \text{if} \quad \exists b_{n+1} \in \{0, 1\} \quad q \xrightarrow{(a, b_1, \dots, b_{n+1})} q'$
 $\qquad \qquad \qquad \text{in } \delta'$

keep some initial state

(Basically take the automaton for $A_{\varphi'}$ and erase the last bit from all transition labels.)

We assumed $A_{\varphi'}$ was a DFA but A_{φ} will likely be an NFA. So if we wish to stick to DFAs, this stage could cause an exponential blow up.

This finishes the $MSO \rightarrow$ automaton construction.

Remarks about complexity:

Q. What about the size of the automata?
(Asymptotic sense)

- How do we construct? NFA or DFA?

DFA \rightarrow \exists is easy but \forall is hard
 \hookrightarrow poly \hookrightarrow exp

NFA \rightarrow \exists is easy but \forall is not

- Size $2^{2^{\dots^2}} \mathcal{O}(n)$ where $n \rightarrow$ size of formula
 \hookrightarrow non-elementary, the length of tower is not fixed

Very bad! :-

Maybe it was our fault? Better construction exists?

Sadly, no. There is a lower bound which is

also non-elementary.

MONA → software that does this translation

Connection between logic and automata very rich. Büchi did this back in '60s. Has been used in formal verification extensively.

Lecture 9 (02-02-2021)

02 February 2021 10:22

Myhill-Nerode Theorem about regular languages

Recap on equivalence relations: Fix a set X . (any cardinality)

Def.: An equivalence relation R on X is a binary relation

$R \subseteq X \times X$ which is

(1) reflexive, i.e., $\forall x \in X : (x, x) \in R$ or xRx ,

(2) symmetric, i.e., $\forall x, y \in X : xRy \Rightarrow yRx$,

(3) transitive, i.e., $\forall x, y, z \in X : xRy \text{ and } yRz \Rightarrow xRz$.

(Equivalence relation, equivalence class)

Fix an equivalence relation R :

For $x \in X$, we define

$[x]_R = \{y \in X : xRy\}$.

By reflexivity, $x \in [x]_R$. In particular, $[x]_R \neq \emptyset$.

Claim. $\forall x, y \in X : [x]_R = [y]_R$ or $[x]_R \cap [y]_R = \emptyset$.

Proof Suppose $[x]_R \cap [y]_R \neq \emptyset$. We show $[x]_R = [y]_R$.

Let $z \in [x]_R \cap [y]_R$.

Thus, xRz and yRz . $yRz \Rightarrow zRy$.

xRz and $zRy \Rightarrow xRy$.

Now, if $y' \in [y]_R$, then yRy' and hence, xRy' .

$\therefore [y]_R \subset [x]_R$. Similarly, $[x]_R \subset [y]_R$. \blacksquare

Thus, the equivalence classes of R partition X .

Usually, we use \sim instead of R to denote an equivalence relation.

Defn: Let \sim be an equivalence relation on X .

$$X/\sim := \{[x]_{\sim} : x \in X\}$$

= the set of all equivalence classes for \sim .

Example: $\mathbb{Z} = \{\dots, -2, -1, 0, 1, 2, \dots\}$.

\sim on \mathbb{Z} : $x \sim y$ iff $3 \mid x-y$.

That is, $\exists m \in \mathbb{Z}$ s.t. $3m = x-y$.

Then, \sim is an equivalence relation.

$$[0]_{\sim} = \{x \in \mathbb{Z} : 0 \sim x\}$$

= $\{x \in \mathbb{Z} : x \text{ is a multiple of } 3\}$

$$= \{\dots, -3, 0, 3, 6, \dots\}.$$

$$[1]_{\sim} = \{\dots, -2, 1, 4, 7, \dots\}$$

$$[2]_{\sim} = \{\dots, -1, 2, 5, 8, \dots\}$$

} all classes

Defn: (Finite index)

We say \sim is of finite index if X/\sim is finite.

Example: \sim on \mathbb{Z} defined above.

Σ^* - the set of all finite words over Σ .

Let \sim be an equivalence relation on Σ^* .

We say:

i) \sim is a right congruence if (right congruence)

$$\forall x, y, z \in \Sigma^* : x \sim y \Rightarrow xz \sim yz$$

2) \sim saturates a language L if (saturates)

$$\forall x, y \in \Sigma^*: x \sim y \Rightarrow (x \in L \Leftrightarrow y \in L)$$

This basically means that either $[x]_\sim \subseteq L$ or $[x]_\sim \cap L = \emptyset$.

In particular, L is the union of ^(some) equivalence classes.

$$L = \bigcup_{x \in L} [x]_\sim \quad (\subseteq, \text{ in general.})$$

Thm. (Myhill-Nerode Theorem)

A language L is regular iff there is a right congruence of finite index which saturates L .

Prof. (\Rightarrow) Let $L = L(A)$ where A is the DFA

$$A = (Q, q_0, \Sigma, \delta: Q \times \Sigma \rightarrow Q, F).$$

We define the relation \sim_A on Σ^* :

$$x \sim_A y \text{ iff } \delta(q_0, x) = \delta(q_0, y).$$

(Extend $\delta(q_0, \cdot)$ inductively on Σ^* .)

The above is indeed an equiv. relation. (Easy.)

• Right congruence: Suppose $x \sim_A y$. Then, $\delta(q_0, x) = \delta(q_0, y)$.

Let $z \in \Sigma^*$ be arbitrary. We note

$$\delta(q_0, xz) = \delta(\delta(q_0, x), z)$$

"

$$\delta(q_0, yz) = \delta(\delta(q_0, y), z)$$

$$\therefore xz \sim_A yz.$$

• Finite index: There are at most $|Q| < \infty$ many states.

• Saturates: $x \in L \Leftrightarrow \delta(q_0, x) \in F$. Conclude. \square

Lecture 10 (04-02-2021)

04 February 2021 11:38

→ Satisfiability problem -

- Is there an algorithm to check if an MSO $[\Sigma]$ -sentence φ is satisfiable?

(Defn) φ is satisfiable if $\exists a$ finite word $w \in \Sigma^*$ such that $w \models \varphi$.

Ans. Yes! $\varphi \rightsquigarrow A_\varphi$ can be done algorithmically.

(Can check if $L(A_\varphi) = \emptyset \leftarrow$ doable.
(decidable))

→ WS1S - weak second order theory of 1 successor

$(\mathbb{N}, +, \cdot) \rightarrow$ first order logic to write properties of natural numbers

$x, y, z, \dots \leftarrow$ first order variables, range over \mathbb{N}

$$x+y=z \mid x \cdot y = z \mid \varphi \vee \varphi \mid \neg \varphi \mid \exists x \varphi$$

$$\text{Zero}(x) \equiv (x+x=x)$$

$$\text{non-prime}(x) \equiv \exists y \exists z (y \cdot z = x) \wedge \neg(y=x) \wedge \neg(z=x)$$

(0 and 1 possibly not considered correctly)

$$\text{even}(x) \equiv \exists y (y+y=x)$$

$$\varphi_0 \equiv \forall x \cdot \text{even}(x) \Rightarrow \exists y \exists z \text{ prime}(y) \wedge \text{prime}(z) \wedge (x=y+z)$$

(Goldbach's conjecture with 0 and 2 accounted for)

(Hilbert, 1900) $S = (\mathbb{N}, +, \cdot)$

$\text{Th}(S) = \left\{ \varphi \text{ a FO sentence which is} \begin{array}{l} \\ \text{true over } (\mathbb{N}, +, \cdot) \end{array} \right\}$

Is there a mechanical procedure (algorithm) for checking if a given FO-sentence is true in $(\mathbb{N}, +, \cdot)$?

$\begin{pmatrix} 1930- \\ 1940 \end{pmatrix}$ Gödel: No.

(Hilbert's dream shattered. \vdash)

(1960s) Büchi : Monadic $\text{Th}(\mathbb{N}, +)$ is also undecidable.

Is Monadic (\mathbb{N}, S) decidable?
 $\uparrow_{\text{successor}}$

$S1S = \{ \varphi - \text{MSO sentence which is true in } (\mathbb{N}, S) \}$

\rightarrow Is $S1S$ decidable? Yes. Büchi showed this.

$\rightarrow W S1S$ — weak $S1S$

In the quantifiers like $\forall X \varphi(X)$, X only ranges over finite subsets of \mathbb{N} .

$(\mathbb{N}, S) \models_{S1S} \exists X \cdot \forall x \cdot X(x)$

$(\mathbb{N}, S) \not\models_{WS1S} \exists X \cdot \forall x \cdot X(x)$

Lecture 11 (08-02-2021)

08 February 2021 09:35

Myhill-Nerode: L is regular iff there is a right congruence of finite index with saturates L .

Proof: Had seen (\Rightarrow) by taking an automaton $A = (Q, q_0, \Sigma, \delta : Q \times \Sigma \rightarrow Q, F)$ and defining $x \sim_A y \equiv \delta(q_0, x) = \delta(q_0, y)$.

(\Leftarrow) Let \sim be a right congruence of finite index

Then, saturates Σ^*/\sim is finite.

Define

$$A_\sim = (Q, q_0, \Sigma, \delta : Q \times \Sigma \rightarrow Q, F)$$

where

$$q_0 = [\epsilon]_\sim,$$

$$\delta : \delta(Q[\#]_\sim, \Sigma) \rightarrow \mathbb{Q} [\# \cdot a]_\sim \text{ defined as}$$

well-defined?

Yes.

If $x \sim y$, then $x \cdot a \sim y \cdot a$ since \sim is a right congruence.

$$F = \{[w]_\sim : w \in L\}.$$

Claim: $L(A_\sim) = L$

Proof: (\supseteq) If $w = a_0 \cdots a_n \stackrel{\epsilon L}{\sim}$, then $\delta(q_0, w) = [a_0 \cdots a_n]_\sim \in F$.

(\subseteq) If $w \in L(A_\sim)$, then $w = a_0 \cdots a_n$ s.t. $[a_0 \cdots a_n]_\sim = [w]_\sim$

for some $w' \in L$. That is, $w \sim w' \in L$. By saturation, $w \in L$. \square

Defn (Syntactic Congruence)

Let $L \subseteq \Sigma^*$ be a language, not necessarily regular.

We define \sim_L on Σ^* as:

$$x \sim_L y \equiv \forall z \in \Sigma^* (xz \in L \Leftrightarrow yz \in L).$$

Straightforward check that:

- \sim_L is an equivalence relation
- \sim_L saturates L (take $z = \epsilon$)
- \sim_L is a right congruence

Ex. "Compute" \sim_L for $L = \{a^n b^n : n \geq 0\}$.

Claim. \sim_L is the coarsest right congruence which saturates L .

(In other words, let \sim be any right congruence saturating L , then $x \sim y \Rightarrow x \sim_L y$. (That is, $[x]_\sim \subseteq [x]_{\sim_L} \forall x$.)

Proof. Let $x \sim y$. To show: $x \sim_L y$.

Let $z \in \Sigma^*$ be s.t. $xz \in L$.

Then, $xz \sim yz$ since \sim is a right cong.

Then, $yz \in L$ since \sim saturates L .

z was arbit. $\therefore \forall z \in \Sigma^* : xz \in L \Rightarrow yz \in L$.

By symmetry, $\forall z \in \Sigma^* : yz \in L \Rightarrow xz \in L$.

Thus, $x \sim_L y$.

□

Note that coarsest means the "fewest" equiv. classes.

Thm. (Myhill-Nerode) L is regular iff \sim_L is of finite index.

Proof. (\Rightarrow) Let A be a DFA s.t. $L = L(A)$.

We had created \sim_A of finite index \rightarrow right congr., sat. L .

Thus, \sim_L is coarser than \sim_A .

$$\therefore |\Sigma^*/\sim_L| \leq |\Sigma^*/\sim_A| < \infty.$$

$\therefore \sim_L$ has finite index as well.

\Leftarrow By Myhill-Nerode.

3

Remark The automaton A_{\sim_L} corresponding to \sim_L is the minimum automaton of L .

Lecture 12 (09-02-2021)

09 February 2021 10:36

\sim is an equivalence relation on Σ^* .

Defn. \sim is a congruence if $\forall x, y, z, w \in \Sigma^*$: (congruence)
 $x \sim y \Rightarrow z x w \sim z y w$.

Thm. L is regular iff there is a congruence of finite index which saturates L .

Proof. (\Leftarrow) Follows from Myhill-Nerode since a congruence is also a right congruence.

(\Rightarrow) $L = L(A)$ where $A = (Q, q_0, \Sigma, \delta: Q \times \Sigma \rightarrow Q, F)$.

Define \sim_A on Σ^* by

$$x \sim_A y \equiv \forall q \in Q: \delta(q, x) = \delta(q, y)$$

[Given any $w \in \Sigma^*$, we get a function $f_w: Q \rightarrow Q$
(effect function)
 $q \mapsto \delta(q, w)$
Now, $w \sim_A w'$ iff $f_w = f_{w'}$, that is, the two functions
are equal.]

$\rightarrow \sim_A$ is an equivalence relation, clearly as can be seen by looking at f_x and f_y .

$\rightarrow \sim_A$ is a congruence: Let $x, y, z, w \in \Sigma^*$ be s.t. $x \sim_A y$.
Then, $f_{z x w} = f_w \circ f_z \circ f_x = f_w \circ f_y \circ f_z = f_{z y w}$

$$\therefore z x w \sim_A z y w.$$

$\rightarrow \sim_A$ is of finite index: There are only $|Q|^{|\Sigma|} < \infty$ many

functions of the form $\Omega \rightarrow \Omega$. Thus, there are at most $|\Omega|^{|\Omega|}$ such distinct effect functions.

$\rightarrow \sim_A$ saturates L : Let $x \sim_A y$.

Then, $x \in L \Leftrightarrow f_x(q_0) \in L \Leftrightarrow f_y(q_0) \in L \Leftrightarrow y \in L$. B

Defⁿ (Syntactic congruence of a language)

Let $L \subseteq \Sigma^*$. $x \sim_L y \equiv \forall z, w \in \Sigma^* (z z w \in L \Leftrightarrow z y w \in L)$

Ex. (1) \sim_L is a congruence which saturates L .

(2) L is regular iff \sim_L is of finite index.

(3) If \sim is a congruence which saturates L , then

$$\forall x, y : x \sim y \Rightarrow x \sim_L y.$$

That is, \sim_L is the coarsest congruence which saturates L .

Defⁿ The syntactic monoid of L

let \sim_L denote the syntactic congruence.

Consider the set $M_L = \Sigma^*/\sim_L$.

$$\cdot : M_L \times M_L \longrightarrow M_L$$

$$(c_1, c_2) \mapsto c_1 \cdot c_2$$

where

$$[w_1]_{\sim_L} \cdot [w_2]_{\sim_L} = [w_1 w_2]_{\sim_L}$$

Well defined: If w, w' and $w_2 \sim w'_2$, then:

$$w, w_2 \sim w, w_2' \sim w', w'_2$$

left cong right cong

Then, $(M_L, \cdot, [\epsilon])$ is a monoid, called the **syntactic monoid** of L .

To see that it is a monoid:

$$\begin{aligned} 1) \text{ Associative: } ([\omega_1] \cdot [\omega_2]) \cdot [\omega_3] &= [\omega_1 \omega_2] \cdot [\omega_3] \\ &= [(\omega_1 \omega_2) \omega_3] = [\omega_1 (\omega_2 \omega_3)] \\ &= [\omega_1] \cdot [\omega_2 \omega_3] = [\omega_1] \cdot ([\omega_2] \cdot [\omega_3]). \end{aligned}$$

Thus, $c_1 \cdot (c_2 \cdot c_3) = (c_1 \cdot c_2) \cdot c_3 \quad \forall c_1, c_2, c_3 \in M_L$.

$$2) \text{ Unital: } [\varepsilon] \cdot [\omega] = [\varepsilon \cdot \omega] = [\omega] = [\omega \varepsilon] = [\omega] [\varepsilon] \quad \forall \omega \in M_L.$$

That is, $c_0 = [\varepsilon] \in M_L$ satisfies $c_0 \cdot c = c = c \cdot c_0 \quad \forall c \in M_L$.

Recall: A **monoid** is a set with a binary operation which is associative and has an identity.

Ex. (1) $(\mathbb{Z}, +, 0)$

(2) $(\mathbb{N}, +, 0)$

(3) $(\Sigma^*, \cdot, \varepsilon)$

(4) any group is a monoid

(5) $(\mathbb{Z}_n, +, 0) \rightarrow$ finite monoid
 $\{0, \dots, n-1\}$ addition modulo n

(6) Fix a set X .

$\mathcal{F}(X)$ = the set of all functions from X to X .

$\circ : \mathcal{F}(X) \times \mathcal{F}(X) \rightarrow \mathcal{F}(X)$

$(f, g) \mapsto f \circ g$

$(\mathcal{F}(X), \circ, \text{id}_X)$ is a monoid.

Thm. L is regular iff M_L is finite.

Lecture 13 (11-02-2021)

11 February 2021 11:31

→ Fix a monoid (M, \cdot, e) .

A **submonoid** of M is a subset $N \subseteq M$ s.t.

(1) $e \in N$

(2) N is closed under \cdot .

More precisely, $(N, \cdot|_N, e)$ is the submonoid.
 $\cdot|_N : N \times N \rightarrow N$ makes sense. Then, a submonoid is
a monoid in itself.

(Submonoid)

Ex. The identity element is unique.

(Proof) $e' = e \cdot e' = e$.

Defn. (Homomorphisms between monoids)

A **(homo)morphism** from (M, \cdot, e) to $(N, *, f)$ is a function $h: M \rightarrow N$ such that

(1) $h(e) = f$

(2) $\forall m_1, m_2 \in M: h(m_1 \cdot m_2) = h(m_1) * h(m_2)$.

Example. ① Let $N \subseteq M$ be a submonoid. Then $i: N \hookrightarrow M$, $n \mapsto n$ is a homomorphism.

② $h: (\Sigma^*, \cdot, \epsilon) \rightarrow (N, +, \cdot)$

$h(x) = \text{length}(x)$ is a morphism.

Defn (Recognise) Let $L \subseteq \Sigma^*$ and $h: \Sigma^* \rightarrow M$ be a morphism.

We say that h recognises L if there is a subset $X \subseteq M$ such that $h^{-1}(X) = L$.

↳ not the same as $X = h(L)$, btw!

Note that if at all, h recognises L , then $X = h(L)$ will work.

We say that L is recognised by M , if there exists a morphism

$h: \Sigma^* \rightarrow M$ that recognises L .

Another way to see: Define \sim_h on Σ^*

$x \sim_h y \text{ if } h(x) = h(y).$
(\sim_h is indeed an equivalence relation.)

$\exists x : h^{-1}(x) = L \text{ iff } \sim_h \text{ saturates } L.$

That is, L is a union of \sim_h equivalence classes.

I'm. L is a regular language iff L is recognised by a morphism into a finite monoid.

Proof. (\Rightarrow) $L = L(A)$ where $A = (Q, q_0, \Sigma, \delta: Q \times \Sigma \rightarrow Q, F \subseteq Q)$.

Notation: Let $x \in \Sigma^*$. $\hat{\delta}_x: Q \rightarrow Q$ is a function
transition/label function of the word x
defined by $\hat{\delta}_x(q) = \delta(q, x)$.

$$\left[\hat{\delta}_{xy} = \hat{\delta}_x \circ \hat{\delta}_y \quad \leftarrow \text{composition in reverse!} \right]$$

(fog)(q) := g(f(q))

Define $M = \{ \hat{\delta}_x \mid x \in \Sigma^* \}$. \leftarrow set of all transition functions

Since $\hat{\delta}_x \circ \hat{\delta}_y = \hat{\delta}_{xy}$, M is closed under \circ .

Moreover, $\hat{\delta}_e$ is the identity function. Thus,

$(M, \circ, \hat{\delta}_e)$ is a monoid.

Moreover, it is finite! (There are at most $|Q|^{|\Sigma|}$ elements.)

Define $h: \Sigma^* \rightarrow M$ by
 $x \mapsto \hat{\delta}_x$.

By construction, h is indeed a morphism.

(Our choice of composition ensures this.)

Define $X = \{\hat{\delta}_n : x \in L\} \subseteq M$.

Then, $h^{-1}(X) = L$.

Proof. (2) clear.

(\Leftarrow) Let $w \in h^{-1}(X)$. Then, $\hat{\delta}_w = \hat{\delta}_n$ for some $x \in L$. Then, $\hat{\delta}_w(q_0) = \hat{\delta}_n(q_0) \in F$. \square

This monoid above is called the transition monoid of the automata A.

(Transition monoid)

(\Leftarrow) Let $h: \Sigma^* \rightarrow M$ be a homomorphism recognising L . (We have $(M, \cdot, e) \leftarrow$ monoid and $X \subseteq M$ s.t.)
 $h^{-1}(X) = L$.

We define the DFA A_h as

$A_h = (M, e, \Sigma, \delta: M \times \Sigma \rightarrow M, X)$ where

δ is defined as

$$\delta(m, a) = m \cdot h(a).$$

Then, $L(A_h) = L$.

Proof. $a_0 \dots a_n \in L(A_h) \Leftrightarrow h(a_0) \dots h(a_n) \in L(A_h)$

$\Leftrightarrow h(a_0 \dots a_n) \in L(A_h)$

$\Leftrightarrow a_0 \dots a_n \in X$

Lecture 14 (15-02-2021)

15 February 2021 09:23

SYNTACTIC MONOID

$L \subseteq \Sigma^*$, for $x, y \in \Sigma^*$: $x \sim_L y$ iff $\forall w \forall z (wxz \in L \Leftrightarrow wyz \in L)$

$$\text{Syn}(L) = (\Sigma^*/\sim_L, \cdot, [\epsilon]_{\sim_L}),$$

\uparrow
syntactic monoid

$$\text{where } [x]_{\sim_L} \cdot [y]_{\sim_L} = [xy]_{\sim_L}.$$

(\sim_L is a congruence, which makes this well-defined)

$$\begin{aligned} \eta_L : \Sigma^* &\longrightarrow \text{Syn}(L) \quad \text{is defined as} \\ x &\longmapsto [x]_{\sim_L}. \end{aligned}$$

Clearly, η_L is a morphism.

η_L is the syntactic morphism. (The quotient morphism.)
(Syntactic morphism)

Universal Property of $\eta_L : \Sigma^* \rightarrow \text{Syn}(L)$:

Suppose $h : \Sigma^* \rightarrow M$ is a monoid morphism which recognises L .

Then, $h(\Sigma^*) \hookrightarrow M$ is a submonoid. We have

$$\Sigma^* \xrightarrow[\text{onto}]{h} h(\Sigma^*) \hookrightarrow M.$$

$\eta_L \Rightarrow \begin{cases} h \\ \hookrightarrow \end{cases} h(\Sigma^*) \xleftarrow[\text{one-one}]{h} M$ \exists a morphism $h_L : h(\Sigma^*) \rightarrow \text{Syn}(L)$
s.t. the triangle commutes.

$$h \circ h_L = \eta_L$$

(recall we write compositions in reverse.)

Def.

We say M divides N if there exists a submonoid P of N and a surjective morphism $h: P \rightarrow M$. Denoted $M \prec N$.

(M divides N)

$$\begin{array}{ccc} P & \hookrightarrow & N \\ \downarrow & & \\ M & & \end{array}$$

Thm

If M recognises L , then $\text{Syn}(L) \prec M$.

↳ in some it is the gcd.

Aim: To analyse $\text{Syn}(L)$ and look at algebraic properties let us see

If L can be recognised by an Fo-formula.

Example

$$\Sigma^* = \{a, b, c\}$$

$\rightarrow L =$ every 'a' is eventually followed by a 'b'.

Ex. Let $L \subseteq \Sigma^*$ be regular. $\text{Syn}(L)$ is the transition monoid of the minimum automaton.

$$\text{Syn } L = \left\{ \begin{array}{ll} \delta_c: p \mapsto p, & \delta_a: p \mapsto q, \\ (\text{identity}) & (\text{label})_1 \\ q \mapsto q, & q \mapsto p \end{array} \right. \quad \left. \begin{array}{l} \delta_b: p \mapsto p \\ q \mapsto p \end{array} \right\} \quad \left. \begin{array}{l} \text{label}_2 \\ \text{label}_3 \end{array} \right.$$

$\left(\begin{array}{l} \text{For any } w, \delta_w \text{ is one of } \delta_c, \delta_a, \delta_b. \\ \text{If } w \in c^*, \delta_w = \delta_c = \text{id}. \text{ Else, look at last non-}c \\ \text{letter. It maps everything to either } p \text{ or } q. \end{array} \right)$

∴ What we have written above is actually $\text{Syn}(L)$.

$$\text{Syn}(L) = (\{e, l, z\}, \cdot, e).$$

$\curvearrowright_{q \rightarrow \text{reset } l}$
 $\curvearrowright_{\cdot \rightarrow \text{reset } p}$

$\hookrightarrow r_2 \rightarrow \text{reset } 1$

$2 \rightarrow \text{reset } p$

← multiplication table

e	1	2
1	1	2
2	2	1

$2 \cdot 1 = \delta_b \circ \delta_a = \delta_{ba} = \delta_a$

The above monoid is called U_2 , the reset-monoid.

Note that $1 \cdot 1 = 1$, $2 \cdot 2 = 2$.

A finite monoid typically has many idempotents.

Also, $x \cdot 1 = 1$ for all $x \in M$.

Defn. An element $m \in M$ is called:

- an **idempotent** if $m \cdot m = m$,
- a **right-zero** if $x \cdot m = m$ for all $x \in M$,
- a **left-zero** if $m \cdot x = m$ for all $x \in M$

(Idempotent, right-zero, left-zero)

Ex. Compute $\text{Syn}(L)$ for $L = (ab)^*, (aa)^* \rightarrow$ list down idempotents

Lecture 15 (16-01-2021)

16 February 2021 10:35

Recall. $U_2 = (\{e, 1, 2\}, \cdot, e)$ where

$$x \cdot m = \begin{cases} x & ; m = e, \\ m & ; m \neq e. \end{cases}$$

That is,

	e	1	2
e	e	1	2
1	1	1	2
2	2	1	1

(Note that since U_2 came from an automaton, assoc. need not be checked.)

Def. A monoid is said to be idempotent if every element is idempotent.

- A monoid (M, \cdot, e) is said to be commutative if $x \cdot y = y \cdot x$ for all $x, y \in M$.

(Idempotent monoid, commutative monoid)

U_2 is commutative since $1 \cdot 2 = 2 \neq 1 = 2 \cdot 1$.

U_2 is idempotent.

$$M = (\{e, p, q\}, \cdot, e)$$

$\xrightarrow{\text{left AND right zero}}$

	e	p	q
e	e	p	q
p	p	p	q
q	q	q	q

Verify that this is associative.

M is both commutative and associative.

Let $\Sigma = \{a, b, c\}$. Let us define

$$h: \Sigma^* \rightarrow M \leftarrow \text{above } M$$

Note that Σ^* is the free monoid on Σ . It suffices

to assign values to Σ . (Any function $f: \Sigma \rightarrow M$ lifts uniquely to a homomorphism $\tilde{f}: \Sigma^* \rightarrow M$.)

We define h by extending

$$a \mapsto p$$

$$b \mapsto q$$

$$c \mapsto r$$

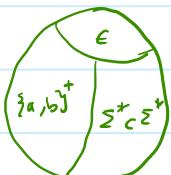

The above specifies h on Σ^* , an infinite set.

$$\text{e.g. } h(ac) = h(a)h(c) = pq = r.$$

$$h^{-1}(e) = \{\epsilon\}$$

$$\begin{aligned} h^{-1}(q) &= \{w \mid w \text{ contains at least one } c\} \\ &= \Sigma^* \setminus \Sigma^c \Sigma^* \end{aligned}$$

$$h^{-1}(p) = \text{non-empty words without a 'c'} = \{a, b\}^+$$

Defn. For a word w , $\alpha(w)$ = the set of letters which appear in w .

Observation: For this above h : $\alpha(w) = \alpha(w) \Rightarrow h(w) = h(w)$.

Lemma. Let M be a commutative and idempotent monoid and

$$h: \Sigma^* \rightarrow M.$$

If $w, w' \in \Sigma^*$ are such that $\alpha(w) = \alpha(w')$, then

$$h(w) = h(w').$$

□

If L is recognised by M and $\alpha(w) = \alpha(w')$,
then $[w \in L \Leftrightarrow w' \in L]$.

Defn. $w \equiv_{\alpha} w'$ if $\alpha(w) = \alpha(w')$.

(This is clearly an equivalence relation.)

This is a congruence on Σ^* .

The equivalence classes of \equiv_{α} are parameterised
by subsets of Σ .

- Obs.
- If L is recognised by a comm. + idem. monoid, then
 L is a union of \equiv -eq. classes.

$$\{w \mid \alpha(w) = A\} = A^* \setminus \bigcup_{a \in A} (A \setminus \{a\})^*$$

- If L is recognised by a comm+idem monoid, then
 L is a boolean combination of languages of the
form A^* for $A \subseteq \Sigma$. Converse also true:

Thm.

L is recognised by a comm. + idem. monoid iff
 L is a boolean combination of languages of the
form A^* where $A \subseteq \Sigma$.

Lecture 16 (18-02-2021)

18 February 2021 11:36

Thm! Let $L \subseteq \Sigma^*$. Then, L is recognised by a commutative monoid iff L is a boolean combination of languages of the form A^* for $A \subseteq \Sigma$.

Proof. (\Rightarrow) $h: \Sigma^* \rightarrow M$ morphism recognising L .

$$\forall w, w' \in \Sigma^*, \alpha(w) = \alpha(w') \Rightarrow h(w) = h(w') \\ \Rightarrow (w \in L \text{ iff } w' \in L)$$

Fix $A \subseteq \Sigma$, note

$$\{w \mid \alpha(w) = A\} = A^* \setminus \left(\bigcup_{a \in A} (A \setminus \{a\})^* \right)$$

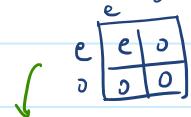

boolean combination

Conclude L is the union of above form.

(\Leftarrow) For A^* , we have $\xrightarrow{\bigcup A} \xrightarrow{\Sigma^{1A}} \bigcup \Sigma$

The corresponding monoid has two elements. It looks

like:

Called \mathbb{U} .

$$\begin{array}{ll} \text{Define } h \text{ by} & \\ a \mapsto e & a \in A \\ a \mapsto o & a \notin A \end{array}$$

Then, $L = h^{-1}(\{e\})$.

- If L is recognised by M , then so is $\bar{L} = \Sigma^* \setminus L$.

- Suppose L_1 and L_2 are recognised by (h_1, M_1, x_1) and (h_2, M_2, x_2) . Then, consider the monoid $M_1 \times M_2$.
 $L_1 \cap L_2$ is recognised by $(h_1 \times h_2, M_1 \times M_2, x_1 \times x_2)$.
 $L_1 \cup L_2$ by $(x_1 \times M_2) \cup (M_1 \times x_2)$.

$L_1 \cup L_2$ by $(X_1 \times M_2) \cup (M_1 \times X_2)$.

$$\left(\begin{array}{l} M_1 \times M_2 : (m_1, m_2) \cdot (m'_1, m'_2) = (m_1 \cdot m'_1, m_2 \cdot m'_2) \\ h_1 \times h_2 : \Sigma^* \rightarrow M_1 \times M_2 \\ w \mapsto (h_1(w), h_2(w)) \end{array} \right)$$

Ex. If M_1 and M_2 are comm + idem, then so is $M_1 \times M_2$.

This finishes the proof. \square

Recall Given monoids M and N , we say M divides N or $M \prec N$ if M is a homomorphic image of a submonoid of N .

$$\begin{array}{c} P \subseteq N \\ \downarrow \\ M \end{array}$$

Lemma If N is comm + idem and $M \prec N$, then M is also comm. + idem.

Proof Let $P \subseteq N$ be a submonoid s.t. $h: P \rightarrow M$.

Note P is also idem + comm.

Now, given $m_1, m_2 \in M$, $\exists p_1, p_2 \in P$ s.t. $h(p_i) = m_i$.

Then $m_1 m_2 = h(p_1) h(p_2) = h(p_1 p_2) = h(p_2) h(p_1) = m_2 m_1$ and $m_1^2 = (h(p_1))^2 = h(p_1^2) = h(p_1) = m_1$. \square

Cor. Given $L \subseteq \Sigma^*$, it has either of the equivalent properties of the Thm 1 iff the syntactic monoid of L is comm. + idemp.

First - Order - Logic

$FO \rightarrow a(n), n < y, n = y, \text{ etc.}$

$FO^1 \rightarrow \text{first order logic with 1 variable}$

never, $x \neq y$, $x = y$, etc.

$Fo^1 \rightarrow$ first order logic with 1 variable

fix the letter: x .

$(\exists x. a(x)) \wedge (\exists x. b(x))$ is fine

$\exists x. (a(x) \wedge b(x))$

becomes very boring $x < x$ always false
 $x = x$ always true

Similarly, we have Fo^2, Fo^3, \dots . Moreover,

$Fo' \subseteq Fo^2 \subseteq Fo^3 \subseteq \dots$. Is this strict?
(expressiveness)

As it turns out, $Fo' \subsetneq Fo^2 \subsetneq Fo^3 = Fo^4 = Fo^5 = \dots = Fo$.
(Wah!!!)

Thm. 2 Let φ be an Fo^1 -sentence and $w, w' \in \Sigma^*$ be s.t.
 $\alpha(w) = \alpha(w')$.

Then, $w \models \varphi$ iff $w' \models \varphi$.

Thm. 3 Let φ be a Fo^1 -formula and $w, w' \in \Sigma^*$
with $\alpha(w) = \alpha(w')$ and i, j are s.t. $w_i = w'_j$.

Then,

$w, x \leftarrow i \models \varphi$ iff $w', x \leftarrow j \models \varphi$

Proof: We prove this by structural induction.

Base case: $\varphi = a(x)$.

Follows since $w_i = w'_j$.

$(w, x \leftarrow i \models a(x) \text{ ift } w_i = a.)$

• $\varphi_1 \vee \varphi_2, \neg \varphi$ follow directly.

• $\varphi = \exists x. \psi(x)$

Assume w, i are s.t. $w, x \leftarrow i \models \varphi$

$w, x \leftarrow i \models \varphi \equiv \exists x. \psi(x)$

$\Rightarrow \exists i' \text{ s.t. } w, x \leftarrow i' \models \varphi$

Note that $\exists j'$ s.t. $w_i = w'_j$ and then

$$(\neg \alpha(w) = \alpha(w'))$$

$w', x \leftarrow j \models \varphi$ and hence,
 $w, x \leftarrow j \models \varphi$

By symmetry, $w, x \leftarrow i \models \varphi$ iff $w', x \leftarrow j \models \varphi$. \square

Thm. Let $L \subseteq \Sigma^*$. TFAE:

- (1) L is definable in $\text{FO}^!$
- (2) L is recognised by a comm. + idem.
- (3) L is a boolean combination of A^* ($A \subseteq \Sigma$)
- (4) $\text{Syn}(L)$ is comm. + idemp.

Lecture 17 (04-03-2021)

04 March 2021 11:43

Defⁿ. A semigroup is a set with an associative binary operation.

(We shall assume non-empty semigroup.)

Any monoid is a semigroup.

(semigroup)

Example. 1) $(\Sigma^+, -)$

2) $(P = \{1, 2, \dots\}, +)$

3)

$$\delta_a : \begin{matrix} 1 \mapsto 1 \\ 2 \mapsto 1 \end{matrix}, \quad \delta_b : \begin{matrix} 1 \mapsto 2 \\ 2 \mapsto 2 \end{matrix}$$

$\{\delta_a, \delta_b\}$ is a semigroup

Not Monoids!
No identity.

Let S be a semigroup. fix $x \in S$.

$X = \{x, x^2, x^3, \dots\}$ is the subsemigroup generated by x .

(It is a cyclic semigroup)

(semigroup generated)

Case 1. All powers are distinct. $x^i \neq x^j$.

Then, X is isomorphic to \mathbb{N} .

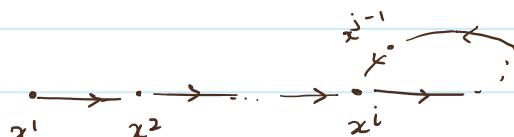

Case 2. There is a repetition in the sequence.

Choose j smallest s.t. $\exists i < j$ with $x^i = x^j$.

Thus, x^1, x^2, \dots, x^{j-1} are all distinct.

This ' i ' (uniquely determined) is called the index of x .

Then, we have a repetition from that point on. (index)

This "loop" has $p = j-i$ elements in it. It is actually a group. p is called the period of x . (period)

Obs. There is a power of x which is an idempotent.

$$x^i = x^{i+p}. \text{ In fact } x^k = x^{k+p} \quad \forall k \geq i.$$

Now, choose q large enough so that $k = qp \geq i$.

Then,

$$(x^k)^2 = x^{2k} = x^{k+qp} = x^{k+qp-p} = \dots = x^k.$$

Thus, k is an idempotent.

Obs: If S is a finite semigroup, then every element x has an idempotent power.

Obs. If S is a finite semigroup then there exists a positive integer π s.t. $\forall x, x^\pi$ is idempotent.

(Note the switch of quantifiers.)

Proof What we know: $\forall x \in S \exists n_x$ s.t. x^{n_x} is idemp.

Let $\pi = \text{LCM}_{x \in S} n_x \leftarrow \text{finite.}$

$$\text{Then, } (x^\pi)^2 = (x^{n_x})^{\pi/n_x} = (x^{n_x})^{\pi/n_x} = x^\pi.$$

Given a semigroup S , we define S' as:

$$S' = \begin{cases} S & \text{if } S \text{ is a monoid} \\ S \cup \{1\} & \text{with the mult. operation on } S \\ & \text{extended to } S \cup \{1\} \text{ so that} \\ & (S \cup \{1\}, \cdot, 1) \text{ is a monoid} \end{cases}$$

$$1 \cdot s = s \cdot 1 = s, \quad s \cdot s' = s' \cdot s \quad \forall s, s' \in S$$

Can check it is associative with 1 as id.

Def. Let S be a semigroup. (right ideal)

A right ideal of S is a subset $R \subset S$ s.t.

$$RS' = R.$$

$$(RS' = \{r \cdot s : r \in R, s \in S'\})$$

Thus, $r, s \in R \quad r \in R, s \in S$

In particular, the same is true for $s \in R$. Thus, R is a semigroup as well.

Def. Similarly, a **left ideal** of S is a subset $L \subset S$ s.t.

$$S' L = L. \quad (\text{left ideal})$$

Def. An **ideal** of S is a subset $I \subset S$ s.t. (ideal)

$$S' I S' = I.$$

We shall assume all types of ideals to be nonempty.

- Fix $x \in S$. What is the smallest right ideal of S which contains x ?

Note that $x \cdot S'$ is a right ideal which contains x .

Moreover, if $R \ni x$ is a right ideal and $y \in S'$, then

$$x \cdot y \in R. \quad \text{Thus, } x \cdot S' \subset R.$$

$\therefore x \cdot S'$ is the right ideal generated by x .

$\rightarrow S'x$ is the left ideal of x .

$\rightarrow S'x S'$ is the ideal of x .

Def. We define the following relations on S :

$x, y \in S$.

$$x \leq_L y \quad \text{if} \quad S'x \subseteq S'y$$

" x is L less than y "

$$x \leq_R y \quad \text{if} \quad x S' \subseteq y S'$$

$$x \leq_S y \quad \text{if} \quad S'x S' \subseteq S'y S'$$

(Script J)

All these three relations are **preorders**. (preorder, pre-order)

[Preorder on a set X : A binary relation which is reflexive and transitive.]

Given a preorder \leq , we get the following equivalence relation \sim by $x \sim y$ iff $x \leq y$ and $y \leq x$.

We can talk of the set of equivalence relations of \sim .

Now, we can define \subseteq on X/\sim by

$$[x] \subseteq [y] \text{ iff } x \leq y.$$

(Is well-defined!)

Now, \subseteq on X/\sim is a partial order.

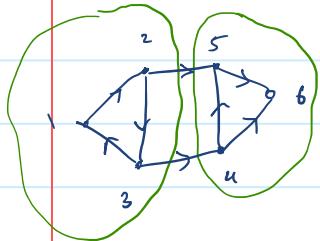

(reflexive, transitive, anti-symmetric)

Example. Let $G = (V, E)$ be a directed graph.

Let \leq on V be defined by

$u \leq v$ if there is a (possibly empty) directed path from u to v .

This is a pre-order. Need not be anti-symmetric.

$$\text{e.g.: } 1 \leq 3, 3 \leq 1, 2 \leq 5, 5 \not\leq 2$$

Now, $u \sim v$ iff $u \leq v$ and $v \leq u$.

Then, $[1] = \{1, 2, 3\} \rightarrow$ "Strongly connected components"
 $[4] = \{4, 5, 6\}$

We get the poset $\{[1], [4]\}$ with $[1] \leq [4]$.

→ directed acyclic graph

Lecture 18 (08-03-2021)

08 March 2021 09:32

Recall: Given $S \leftarrow$ semigroup, we defined S' and the pre-orders
 \leq_L, \leq_R, \leq_J as

$$\begin{aligned} s \leq_L s' &= S^1 s \subseteq S s', \\ s \leq_R s' &= s S^1 \subseteq s' S^1 \\ s \leq_J s' &= S^1 s S^1 \subseteq S^1 s' S^1. \end{aligned}$$

The associated equivalence relations by the letters
 L, R, J , resp. That is:

$$\begin{aligned} s L s' &\Leftrightarrow (s \leq_L s' \text{ and } s' \leq_L s) \Leftrightarrow S^1 s = S^1 s' \\ &\Leftrightarrow \exists m, n \in S^1 \text{ s.t. } s = ms' \text{ and } s' = ns. \end{aligned}$$

$$\text{Similarly, } s R s' \Leftrightarrow s S^1 = S^1 s' \Leftrightarrow \exists m, n \in S^1 \text{ s.t. } s = s'm \text{ and } s' = sn.$$

$$\text{Lastly, } s J s' \Leftrightarrow S^1 s S^1 = S^1 s' S^1 \Leftrightarrow \exists m, m', n, n' \in S^1 \text{ s.t. } \\ s = m's'm \text{ and } s' = n's'n.$$

For an element $s \in S$: $L(s), R(s)$, and $J(s)$ denote the equivalence class containing s corresp. to L, R, J .

Lemma: The relations \leq_R and R are stable on the left.

That is, $\forall s, x \in S$, we have

$$\begin{aligned} s \leq_R s' &\Rightarrow xs \leq_R x s' \text{ and} \\ s R s' &\Rightarrow xs R x s'. \end{aligned}$$

Similarly, \leq_L and \geq are stable on right.

Prof $s \leq_R s' \Leftrightarrow ss^1 \subseteq s's^1 \Leftrightarrow \exists m \in s^1 \text{ s.t. } s = s'm$

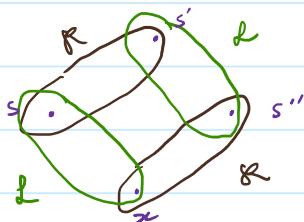

Now, $x \in S$ gives $xs = xs'm \in (xs')s^1$.
 $\Rightarrow xsS^1 \subseteq (xs')S^1$
 $\Rightarrow xs \leq_R xs'$.

This gives that R is left stable to. \square

Lemma The relations R and L commute.

If $s, s', s'' \in S$, we have

$$sR s' \text{ and } s'L s'' \Rightarrow \exists x \in S \text{ s.t. } sLx \text{ and } xR s''.$$

Prof $sR s' \Rightarrow \exists m, n \quad s = s'm, \quad s' = s_n$

$$s'L s'' \Rightarrow \exists p, q \quad s' = ps'', \quad s'' = qs'$$

$$\begin{aligned} \text{Let } x &= qs'm = s''m \in s''S^1 \\ &= q_s \in S^1 s \end{aligned}$$

$$\begin{aligned} \text{Now, } px &= pq s'm \\ &= ps''m = s'm = s. \end{aligned}$$

$$\text{Thus, } s = px \in s^1 x.$$

$$\therefore s \geq x. \quad \text{Hence } xR s''.$$

$\therefore s \mathcal{L} x \quad ||^{\text{by}} \quad x \mathcal{R} s''$

- Suppose we have R_1 and $R_2 \rightarrow$ equiv. relations on X . We want the smallest equiv. rel^h which contains R_1 and R_2 .

This becomes easier if R_1 and R_2 commute.

Defn.: Denote by \mathcal{D} the equivalence relation $R \mathcal{L} (= \mathcal{L} R)$, i.e., $x \mathcal{D} z$ iff $\exists y \text{ s.t. } x R y \text{ and } y \mathcal{L} z$.

This is an equivalence relation since R and \mathcal{L} commute.

$x \mathcal{D} x$ since $x R x \mathcal{L} x$.

$$x \mathcal{D} z \Rightarrow \exists y \ x R y \mathcal{L} z \Rightarrow \exists y' \ x R y' \mathcal{L} z \Rightarrow z R y' \mathcal{L} x \\ \Downarrow \\ z \mathcal{D} x$$

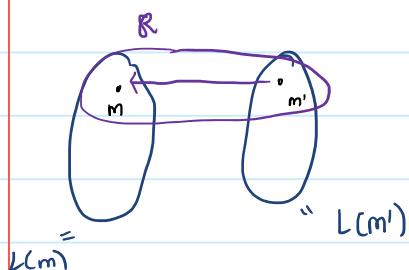

$$x_1 \mathcal{D} x_2 \mathcal{D} x_3 \Rightarrow x_1 R y_1 \mathcal{L} x_2 R y_2 \mathcal{L} x_3 \Rightarrow x \mathcal{L} y_3 R x_2 R y_2 \mathcal{L} x_3 \\ \Downarrow \\ x_1 \mathcal{D} x_3 \Leftarrow x R y_3 \mathcal{L} x_3 \Leftarrow x R y_1 \mathcal{L} y_2 \mathcal{L} x_3 \Leftarrow x \mathcal{L} y_3 R y_2 \mathcal{L} x_3$$

Defn.: Denote by \mathcal{H} the equivalence relation $R \cap \mathcal{L}$.

Lemma: Let $D \subseteq S$ be a \mathcal{D} class and let $m, m' \in D$ be s.t. $m \mathcal{R} m'$.

Further, choose p and q s.t. $m = m'p$ and $m' = mq$.

Follows from commutativity Then, $x \mapsto xp$ is a map $L(m') \rightarrow L(m)$ and $x \mapsto xq$ is a map $L(m) \rightarrow L(m')$.

Moreover, these are inverses of each other. (In particular, they are bijections.)

Furthermore, they preserve \mathcal{H} classes.

Proof.

Let $n \in L(m)$. $[m \not\sim n]$

Write $n = sm$.

$$\text{Now, } (nq)p = smqp = sm'p = sm = n.$$

This shows that the maps are inverse. (By symmetry.)

Lecture 19 (09-03-2021)

09 March 2021 10:34

Green's relation : $\leq_L, \leq_R, \leq_T, L, R, T$.

(1) \leq_R, R stable on right, ...

(2) L and R commute.

$$\text{Ex. } (\leq_L) \circ (\leq_R) = \leq_T = (\leq_R) \circ (\leq_L)$$

$$(3) D = L \circ R = R \circ L.$$

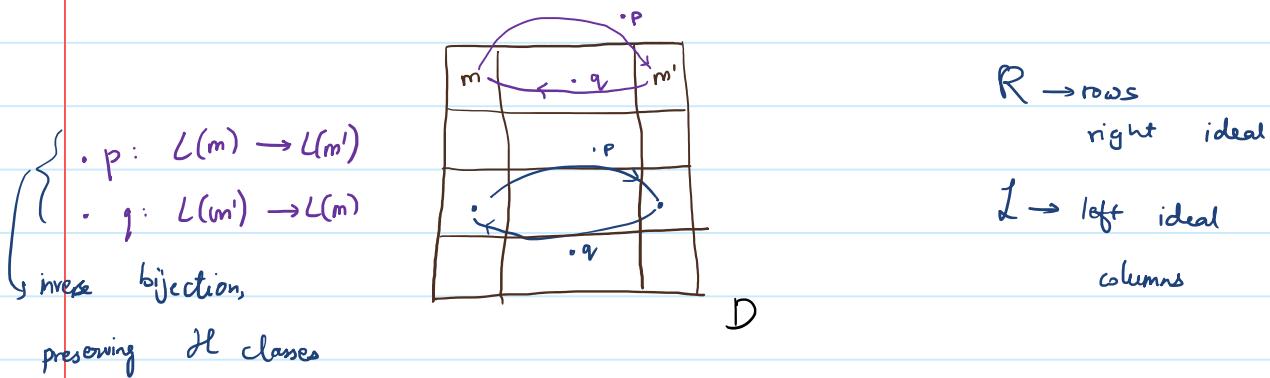

Note that $D \subseteq T$ in general but $D \neq T$ not necessary.

However, $D = T$ for finite semigroups

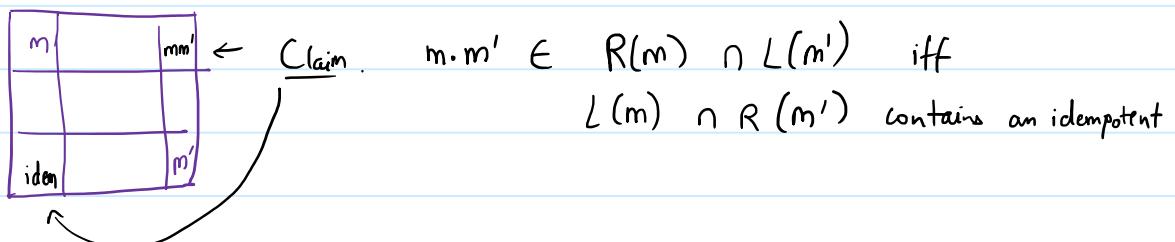

$$(4) H = L \cap R.$$

(5) Let D be a D -class, $m, m' \in D$ and $m R m'$.

Fix $p, q \in S^2$ s.t. $m' = mp$ and $m = m'q$.

(6) Let D be a D class; $m, m' \in D$.

Prove. (\Rightarrow) $\cdot m': L(m) \rightarrow L(mm')$ is a bijection, by the previous.

But $L(m \cdot m') = L(m)$.

Moreover, $\cdot m'$ preserves \mathcal{H} classes.

$\therefore \exists e \in L(m) \cap R(m')$ such that

$$e \cdot m' = m'$$

As $e \not\in m'$, $\exists x$ s.t. $m'x = e$.

Now, $e \cdot e = e \cdot (m'x) = (e \cdot m')x = m' \cdot x = e$.

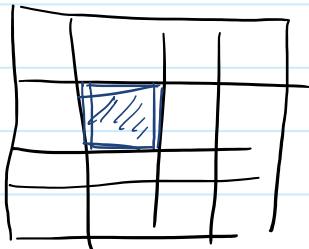

(\Leftarrow) Let $e \in L(m) \cap R(m')$ be an idempotent.

$\left. \begin{array}{l} e \not\in m' \\ e \cdot e = e \end{array} \right\} \Rightarrow \exists x \quad ex = m'$
Note $em' = e(ex) = e^2x = ex = m'$.
Thus, we may assume $x = m'$.

$\cdot m' : L(m) = L(e) \longrightarrow L(m')$ is an \mathcal{H} -class
preserving map (in fact, a bijection)

$\Rightarrow m \cdot m' \in R(m) \cap L(m')$. ◻

(\Rightarrow) An \mathcal{H} -class H is a group (under the induced operation)
iff it contains the product of two of its elements.
(iff it contains an idempotent)

(\Leftarrow) Trivial.

(\Leftarrow) Let $m, m' \in H$ be s.t. $m \cdot m' \in H$.

But then we are in the previous scenario. (Degenerate rectangle.)

Thus, H contains an idempotent, say e .

Now, $\forall x \in H : xe = x = ex$. (Use the trick from earlier!)

$(x \in H \Rightarrow x \not\in e \text{ and } xe \in e \Rightarrow \exists m', m'' \text{ s.t. } x = em' = m''e)$
but we can choose both to ...

$(x \in H \Rightarrow xRx \text{ and } \text{ide} \Rightarrow \exists m', m'' \text{ s.t. } x = e m' = m'' e)$
 but we can choose both to x .

Now $\cdot x : H \rightarrow H$ is a bijection. $\therefore \exists y \in H \text{ s.t.}$

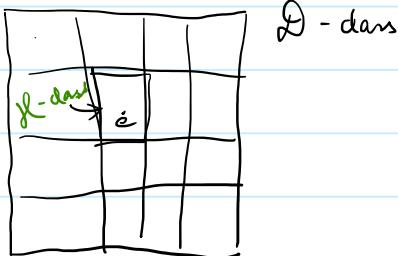

$$yx = e.$$

Similarly, so is $x \cdot : H \rightarrow H$. $\therefore xz = e \text{ for some } z$.

Thus, every elt has a left as well as right inverse.

Visual algebra tells us that they are same. \square

(8) "egg-box" picture

All H -classes within a D class have same cardinality.
 (Possibly different across diff. D classes.)

If D contains an idempotent, it contains at least one idempotent in each R -class and each D -class.

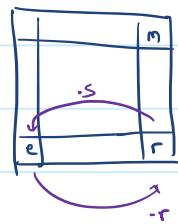

(Thus, if a D class contains one idem., so does every row and column.)

Proof: Let $e \in D$ be an idempotent.

Let $m \in D$.

$\exists r \text{ s.t. } e R r \not\sim m$.

$$e \cdot r = r \quad (\text{since } e \text{ is idemp.}) \quad (\text{same trick})$$

$$\exists s \text{ s.t. } r \cdot s = r. \quad \text{Now,}$$

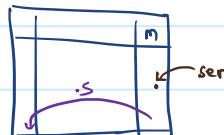

$$(ser)^2 = serser = s e^2 r = ser.$$

Thus, ser is an idempotent. Note $er = r$ and thus,
 $ser = sr$.

Claim: $r \not\sim (ser)$.

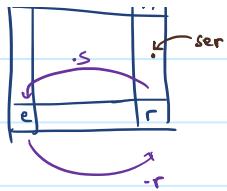

Proof: $ser = (se)r \quad \text{--- (1)}$

$\dots \sim \dots \sim \dots \sim \dots$

Proof.

$$\begin{aligned} ser &= (se)r \quad - (1) \\ r(sr) &= (rs)er = e^2r = r \\ \Rightarrow r &= (r)ser \quad - (2) \end{aligned}$$

(1) and (2) show that $r \leq (ser)$. \square

Thus, the column $L(m)$ contains an idempotent.
Hence, $R(m)$ contains one. \square

Lecture 20 (11-03-2021)

11 March 2021 11:36

Falling down in pre-orders:

- right multiplication makes you fall down in \leq_R .
That is, if $x \in S$, $y \in S^1$, then $xy \leq_R x$.
- left multiplication makes you fall down in \leq_L .
 $= x \xrightarrow{f_L} x$ for $x \in S$, $z \in S^1$.
- Similarly, $zxy \leq_R x$.

Note $x \mathcal{D} y \Rightarrow x \mathcal{T} y$

$$x \mathcal{D} z \mathcal{R} y \Rightarrow s'x = s'z, zS' = yS' \Rightarrow s'xs' = s'zs' = s'ys'$$

Converse not true in general. Is true when $|S| < \infty$.

From now, S will denote a finite semigroup.

Lemma. (Simplification lemma) Let $m \in S$, $x, y \in S^1$.

If $xmy = m$, then $m \mathcal{L} xm$ and $m \mathcal{R} my$.

(We do always have $xm \leq_R m$. Here, $xm \leq_R m \leq_R xm$.)

Proof: $m = xmy$

$$= x(xmy)y = x^2my^2 = \dots = x^3my^3 = \dots = x^lmy^l$$

$\forall l \geq 0$

Recall that every element in finite semi. has idemp. power.

Let $i, j > 0$ be s.t. x^i, y^j are idempotent.

$$x^i = x^{2i} = x^{3i} = \dots = x^{ii}, \quad y^j = y^{2j} = \dots = y^{ij}$$

$$\begin{aligned} m &= x^{ij} m y^{ij} = x^i x^{ij} \cdot m \cdot y^{ij} \\ &= x^i \cdot m = x^{i-1} \cdot (xm) \end{aligned}$$

$$\Rightarrow m \leq_L xm.$$

$$\therefore m \not\leq_L xm.$$

Similarly, $m R my$. ◻

Lemma: $m \mathcal{T} m' \Rightarrow m \mathcal{D} m'$

Proof: $m \mathcal{T} m' \Rightarrow \exists x, y, a, b, \quad m = xm'y \wedge m' = amb$.

$$m = xm'y = (xa)m (by)$$

By simplification, $m \not\leq_L (xa) \cdot m, \quad m R m (by)$.

$$m \leq_L (xa) \cdot m \leq_L am \leq_L m.$$

$$\Rightarrow m \not\leq_L am. \quad \text{Similarly, } m R mb.$$

$$am R amb$$

$$\Rightarrow m \not\leq_L am R amb \Rightarrow m \mathcal{D} amb = m'.$$

$\therefore m \mathcal{D} m', \text{ as desired. } \square$

Lemma: Suppose $m \mathcal{T} m'$ (and hence, $m \mathcal{D} m'$).

(i) If $m \leq_R m'$, then $m R m'$.

Thus, two R classes within a T class are incomparable.

(ii) If $m \leq_L m'$, then $m \not\leq_L m'$.

Proof: We only prove (i).

$m \sqsupseteq m'$ and $m \leq_R m'$.

$m = m'x$ for some $x \in S^1$. $(\because m \leq_R m')$

$m' = amb$ for some $a, b \in S^1$. $(\because m' \leq_R m)$

$m' = am'xb$. Apply simplification to get
 $m' \not\sim_R m'xb$.

$$m' \leq_R m'xb \leq_R m'x \leq_R m'.$$

$$\therefore m' R m'x = m.$$

□

Defn. A finite semigroup S is **aperiodic** if $\exists n > 0 \forall x \in S : x^n = x^{n+1}$,
or $\forall x \in S \exists n > 0 : x^n = x^{n+1}$.

(aperiodic)

(both are equivalent since S is finite)

Prop Let S be a finite semigroup.

TFAE:

- (i) S is aperiodic. "each element has period 1"
- (ii) Each element generates a sub-semigroup of period 1.
- (iii) Each \mathcal{J} -class of S is trivial.
- (iv) Every group in S is trivial. [Group free semigroup.]

Proof. (i) \Rightarrow (ii) trivial, the loop of length p repeats.

if $p \neq 1$, it will never be $x^n = x^{n+1}$.

(iii) \Rightarrow (iv) a maximal group in a semigroup is an \mathcal{J} -class.
(general)

(iv) \Rightarrow (i) we showed the loop forms a group.

(ii) \Rightarrow (iii) next class

Lecture 21 (15-03-2021)

15 March 2021 09:23

(ii) \Rightarrow (iii) Have : Each element has period 1

To show : \mathcal{R} relation is trivial.

Let $a \mathcal{R} b$. That is, $S^1 a = S^1 b$ and $a S^1 = b S^1$.

$\exists x, y \in S^1$ s.t. $x a = b, y b = a$.

$\exists p, q \in S^1$ s.t. $a p = b, b q = a$

$$\begin{aligned} \text{Thus, } b &= xa = xbq \quad \Rightarrow b = xbq \\ &= x^2 b q^2 \\ &= \dots = x^n b q^n \quad \forall n \geq 1 \end{aligned}$$

We know that q has period 1. Thus, $\exists m \geq 1$ s.t. $q^m = q^{m+1}$.

$$\begin{aligned} b &= x^m b q^m = x^m b q^{m+1} \\ &= (x^m b q^m) q = b q = a. \end{aligned}$$

(iii) \Rightarrow (iv) [More elaboration]

Let $G \subseteq S$ be a group.

We show $g \mathcal{R} e \wedge g \in G$. (e is identity of G .)

(Since \mathcal{R} classes are trivial, we would get $G = \{e\}$)

Let $g \in G$ be arbitrary. Then, $\exists g' \in G$ s.t. $g \cdot g' = e = g \cdot g'$.

Thus, we get: (*) $g \cdot g' = e$ (*) $g' \cdot g = e$

(*) $g \cdot e = g$ (*) $e \cdot g = g$

Thus, $g R e$ and $g L e$.

In general, \mathcal{R} -classes containing an idempotent are maximal groups in S .

in S.

Schutzenberger's Theorem

→ A language is recognised by an aperiodic monoid/semigroup iff it is expressed by a star-free expression.

→ [McNaughton-Papert Theorem]

Star-free \equiv first-order logic definability

Fix Σ finite. Star-free:

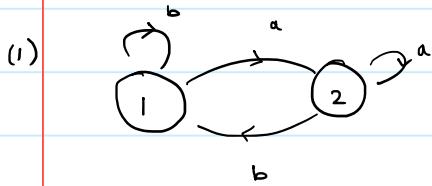

$$r = r_1 + r_2 \mid \neg r \mid r_1 \cap r_2 \mid r_1 \cdot r_2 \mid a \in \Sigma \mid \emptyset \leftarrow \text{star-free}$$

Ext. reg. exp.	Logic	Algebra	Automata
General reg. exp	MSO	finite monoid/semi-group	DFA, NFA
Star-free	Fo	aperiodic mon/semi	counter-free act.

Lecture 22 (16-03-2021)

16 March 2021 10:31

Examples of Green's relation

	1	2
$\epsilon = 1$	1	2
a	2	2
b	1	1

(transition functions:) $aa = a$, $bb = b$, $ab = b$, $ba = a$

$$M = \{1, a, b\}$$

Now, words of length ≥ 3 can be reduced to a or b

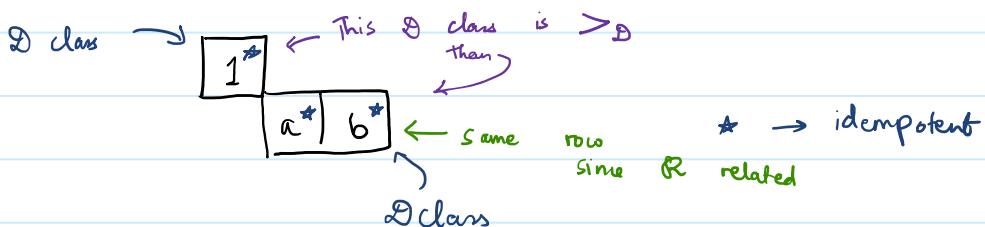

$$M_1 M = M$$

$$M_a = \{a\} ; M_b = \{b\} ; \text{ Thus, } a \not\sim b.$$

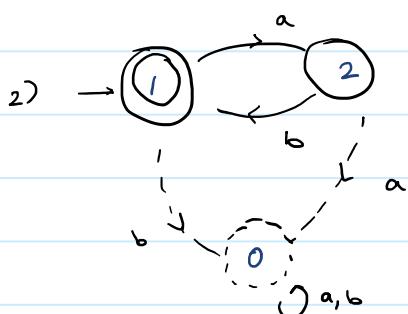

$$aM = \{a, b\} = bM ; \text{ Thus, } a R b.$$

$$M_a M = \{a, b\} = M_b M ; \text{ Thus, } a T b.$$

Thus, \mathcal{H} is trivial. ($\because M$ is aperiodic.)

Another way to get $a R b$ is : $b = ab \leq_R a$ and $a = ba \leq_R b$.

$$L \leftrightarrow (ab)^*$$

The 0 and bottom transitions are just to determinize. Will ignore in future.

$E = 1$	1	2	(not writing 0 column since) obvious.
a	2	0	
b	0	1	
ab	1	0	
ba	0	2	
aa	0	0	
bb	0	0	

→ reset to sink

Let $0 := aa (= bb)$.

Note $wvw = 0 \quad \forall w, v \in \Sigma^*$.

Now, $aba = a, bab = b$.

Thus, everything can now be reduced.

$$M = \{1, a, b, ab, ba, 0\}.$$

$$aa = bb = 0.$$

$$aba = a, bab = b.$$

} presentation

$$aabba = 0ba = 0$$

$$\left. \begin{array}{l} ab \leq_R a \\ a = ab \cdot a \leq_R ab \end{array} \right\} aRab$$

$$b = bab \stackrel{R}{\leq} ba \leq_R b \Rightarrow bRba$$

1^*	
↑	
a	ab^*
ba^*	b

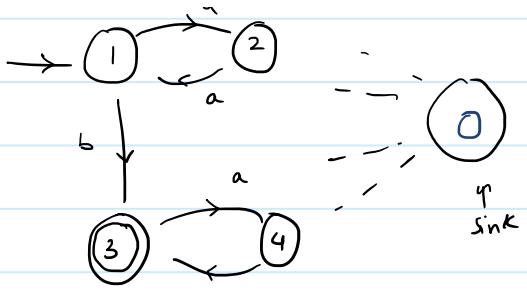

$$a = aba \leq_L ab \leq_L a$$

: a $\not\leq_L$ ab

↑↑↑ b $\not\leq_L$ ba

↑ denotes that the above is \leq_D then below.

$$3) K = \{a^i b a^j \mid i \equiv 0 \pmod{2}, j \equiv 0 \pmod{2}\}.$$

$$bb = 0, \quad aa = 1$$

Now, we look at three letter words w/o "aa" & "bb".

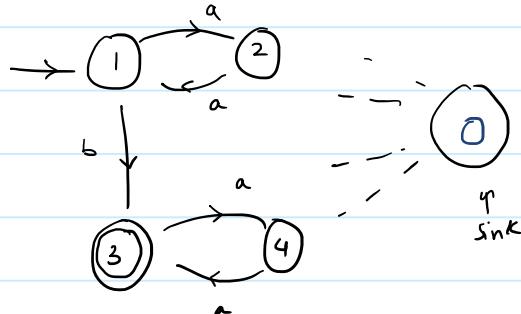

1	1	2	3	4
a	2	1	4	3
b	3	0	0	0
ab	0	3	0	0
ba	4	0	0	0
<hr/>				
$0 = bb$	0	0	0	0
$t = aa$	1	2	3	4
<hr/>				
aba	0	1	2	3
<hr/>				
0	0	0	0	0

Lecture 23 (18-03-2021)

18 March 2021 11:35

Green's Relations

$$K = \{ a^i b a^j \mid i \equiv 0 \pmod{2}, j \equiv 0 \pmod{2} \}.$$

$$bb = 0, aa = 1$$

Now, we look at three letter

words w/o "aa" & "bb".

1	1	2	3	4
a	2	1	4	3
b	3	0	0	0
ab	0	3	0	0
ba	4	0	0	0
$\theta = bb$	0	0	0	0
$t = aa$	1	2	3	4
aba	0	4	0	0
$\theta \leftarrow bab$	0	0	0	0

$$bb = 0, aa = 1, bab = 0$$

$$M = \{1, a, b, ab, ba, aba, 0\} \quad \left. \begin{array}{l} \\ \end{array} \right\} \text{ gives complete description}$$

$$bb = 0, aa = 1, bab = 0$$

$$a^2 = 1. \quad \text{Thus, } 1 \leq_R a \leq_R 1 \text{ and same for } L.$$

$$\therefore a R 1 L a \text{ and thus, } a \not\leq 1.$$

$$\Rightarrow 1 \not\leq a.$$

First example where there is an \leq class with >1 element.

Thus, it is not aperiodic.

Def. A class (\emptyset, L, R, \leq) is called regular if it contains an idempotent.

Claim. Let M be a finite monoid.

Then, $J(1) = H(1)$.

Proof. $x J 1 \Rightarrow x D 1$ [M is finite]

(We saw $a J b$ and $a \leq_R b$, then $a R b$.)

Thus, $x R 1$. ($x \leq_R 1$ always true.)

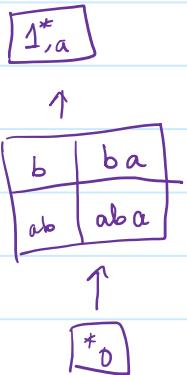

Similarly, $x L 1$

Thus, $x H 1$. □

Back to example:

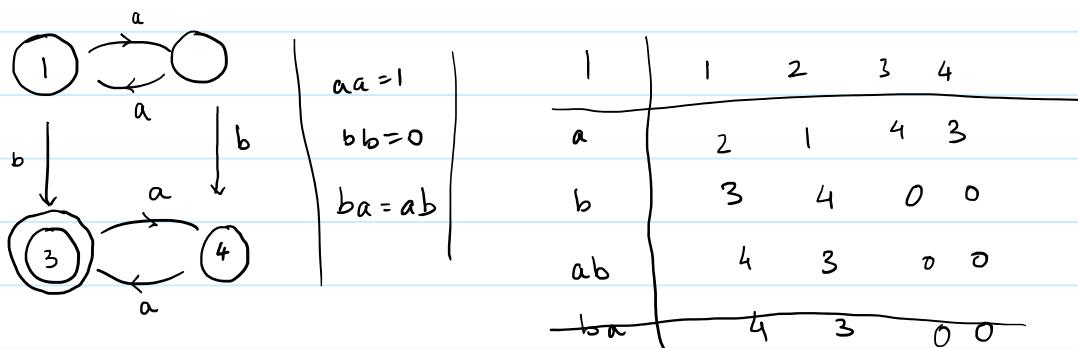

$$b = a \cdot ab \leq_L ab \leq_L b. \quad \therefore b L ab.$$

$$b = ba \cdot a \leq_R ba \leq_R b. \quad \therefore b R ba$$

(Show: $b R ab$ and $b \not R ba$)

$$\cdot L = \{ a^i b a^j \mid i + j \equiv 0 \pmod{2} \} \subseteq K$$

Now, all 3 letter words are done too.

$$aba = aab = b, \quad bab = bba = 0$$

$$N = \{1, a, b, ab, 0\}.$$

$$aa = 1, bb = 0, ba = ab.$$

$1 \not\sim a, a \sim$ before.

$$ab \leq_L b = aab \leq_L ab. \quad \therefore b \not\sim_L ab$$

$$b = aab = aba \leq_R ab = ba \leq_R b. \quad \therefore b \not\sim_R ab.$$

$\boxed{1, a}$

$\boxed{b, ab}$

$\boxed{0}$

$$(ab)(ab) = abab = aabb = 0 \neq ab$$

Schützenberger: Star-free regex \equiv recognised by an aperiodic monoid
(Finite monoid)

- A language L has a star-free regex iff Σ^*/\sim_L is aperiodic.

① L is star-free $\Rightarrow L$ can be recognised by an aperiodic monoid.

Will do this by induction. We had seen how products recognise union/intersection. Some monoid accepts complement.

Need to show for concat. Need to make sure aperiodicity is maintained.

Not difficult. Will do in fact.

② (\Leftarrow) This is the difficult direction.

L recognised by aperiodic monoid $\Rightarrow L$ is star-free.

Will also show FO-definability.

$$h: \Sigma^* \rightarrow M, \quad L = h^{-1}(x) \text{ for some } x \in M$$

(finite) $\stackrel{\text{aperiodic}}{\sim}$

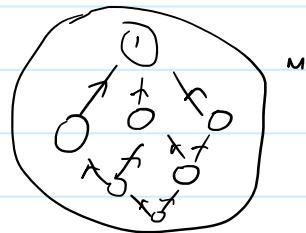

We show: $\forall m \in \mathbb{N}$, $h^m(\{y\})$ is a star-free language.

From the above, the result follows.

Will use \leq_j to do induction.

Top class will only contain

1 since $J(1) = h(\lambda) = \{y\}$
aperiodic

$$h^{-1}(\{y\}) = ?$$

Suppose $a_1, \dots, a_n \in h^{-1}(\{y\})$.

$$\text{Then, } h(a_1, \dots, a_n) = 1$$

$$\Rightarrow h(a_1) \cdots h(a_n) = 1$$

$$\Rightarrow h(a_i) \leq 1 \quad \forall i$$

$$\Rightarrow h(a_i) = 1 \quad \forall i$$

$$\therefore h^{-1}(\{y\}) = A^* \quad \text{where} \quad A = \{a \in \Sigma : h(a) = 1\}.$$

$$= \gamma \left(\bigcup_{b \notin A} \Sigma^* b \Sigma^* \right).$$

Lecture 24 (22-02-2021)

22 March 2021 09:32

Schutzenberger's Theorem

Difficult direction: Aperiodic \Rightarrow star-free

Let $h: \Sigma^* \rightarrow M$ be a morphism to a finite aperiodic monoid.
We will show: $(*) \forall m \in M, h^{-1}(\{m\})$ is star-free. (SF)

Define: $m <_g m'$ if $m \leq_g m'$ and $\neg(m \geq_g m')$.
(Antisymmetric, irreflexive, transitive.)

We will prove $(*)$ by induction on $<_g$.

More precisely:

Base: 1) $h^{-1}(1)$ is SF.

Induct: 2) $\forall m \in M [(h^{-1}(n) \text{ is SF } \forall n >_g m) \Rightarrow (h^{-1}(m) \text{ is SF})]$.

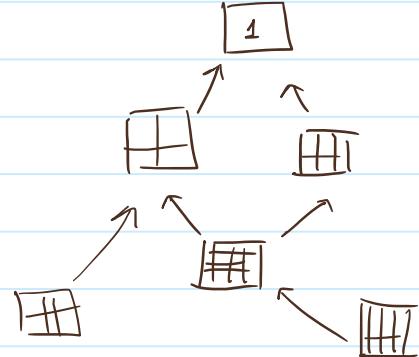

Note that $J(1) = H(1)$ is trivial. Thus, The topmost J -class contains only 1.

Base case:

$h^{-1}(\{1\}) = A^*$ where $A = \{a \in \Sigma : h(a) = 1\}$.

A^* is star-free. (J -class of 1 is trivial again.)

$$A^* = \overline{\phi} \left(\overline{\phi} \left(\sum_{a \notin A} a \right) \overline{\phi} \right)$$

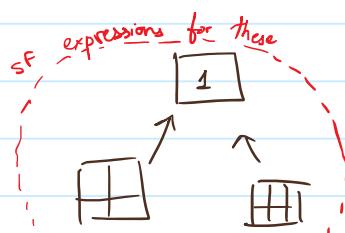

Induction step. Notation: $L_m = h^{-1}(\{m\}) = \{w \in \Sigma^* : h(w) = m\}$.

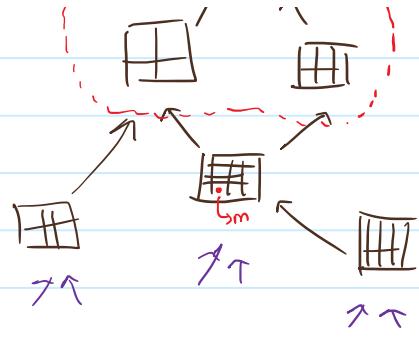

Fix an element $1 \neq m \in M$.

Assume: $\forall n >_g m, L_n$ is SF.

To show: L_m is SF.

To show L_m is SF.

Step 1

$$L_{J(m)} := \{w \in \Sigma^* : h(w) \in J_m\} \text{ is SF.}$$

Step 2

$$L_{R(m)} := \{w \in \Sigma^* : h(w) \in R_m\} \text{ is SF.}$$

Step 3

$$L_{L(m)} := \{w \in \Sigma^* : h(w) \in L_m\} \text{ is SF.}$$

Step 4

$$\begin{aligned} L_{H(m)} &:= \{w \in \Sigma^* : h(w) \in H_m\} \text{ is SF} \\ &= L_{R(m)} \cap L_{L(m)}. \end{aligned}$$

Steps 2 and 3 \Rightarrow Step 4.

Step 5. By aperiodicity, $H(m) = \{m\}$. Thus, Step 4 shows L_m is SF.

Step 1. $L_{\neq m} = \{w \in \Sigma^* : h(w) \neq m\}$.

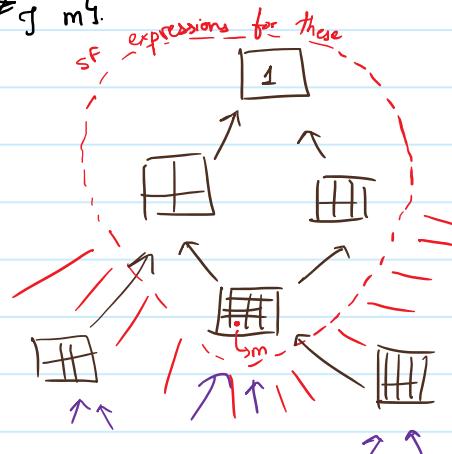

Claim. $L_{\neq m}$ is SF.

Note: $L_{J(m)} = (L_{\neq m})^c \setminus \left(\bigcup_{n \geq m} L_n \right)$

we show this is SF

by induct, SF

Thus, $L_{J(m)}$ is SF.

Proof (of claim). Note that $I = \{n : n \neq m\}$ is an ideal of M . $L_{\neq m} = h^{-1}(I)$.

Thus, $L_{\neq m}$ is again an ideal.

(In other words, $w \in L_{\neq m}$ and $x, y \in \Sigma^* \Rightarrow xwy \in L_{\neq m}$.)

Consider a word $w \in L_{\neq m}$ and consider a minimal factor u of w s.t. $u \in L_{\neq m}$. (Such a factor must exist. . . w is one such. . . there are only finitely)

of w s.t. $u \in L_{\geq j, m}$. (Such a factor must exist. w is one such.
there are only finitely many.)

By minimality of u , no proper factor of u is in $L_{\geq j, m}$.

($u \neq \epsilon$ since $h(\epsilon) = 1 \geq j, m$)

Case 1. $|u| = 1$. $h(u) \not\geq j, m$.

$u = a \in \Sigma$, $h(a) \not\geq j, m$. Then, $w \in \Sigma^* \xrightarrow{SF} \Sigma^*$, where
 $X_m = \{a \in \Sigma : h(a) \not\geq j, m\}$

Conversely, all words here map to I

Case 2. $|u| \geq 1$.

Write $u = avb$ for $a, b \in \Sigma$ and $v \in \Sigma^*$.

$h(u) \not\geq j, m$ but $h(av), h(v), h(vb) \geq j, m$, by minimality.

Claim. $h(v) >_j m$.

Proof. Suppose not. Then, $h(v) \leq m$.

Then, $h(av) \leq m$ and $h(vb) \leq m$ as well.
 $(m \leq h(v) \geq h(av) \geq m)$

Thus, $h(v) \leq h(vb)$. (Clearly, $h(v) \geq h(vb)$).

Since M is finite, we get

$$h(v) \leq h(vb)$$

In turn, $h(av) \leq h(avb) = h(u)$

$$\Rightarrow h(av) \leq h(u).$$

$$\Rightarrow h(av) \leq h(u).$$

$$\Rightarrow m \leq h(u).$$

→ ←

Thus, $h(v) >_j m$. Thus, $v \in \bigcup_{n > j, m} L_n$.

→ SF language,
by induction

$\therefore u \in \bigcup_{\substack{a, b \in \Sigma \\ n > j, m}} a \cdot L_n \cdot b$

$$\begin{aligned}a, b \in \Sigma \\n \geq j^m \\h(a) \cdot n \cdot h(b) \neq j^m\end{aligned}$$

Conversely, all words here map to the ideal I

We have shown that $L_{p_{j^m}}$ is ST.

This $L_{j(m)}$ is S.F. This finishes Step 1.

Lecture 25 (23-03-2021)

23 March 2021 10:39

Step 2. $L_{R(m)}$ is SF.

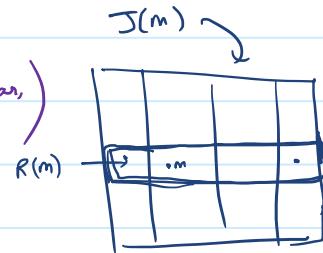

$$L_{R(m)} \subseteq L_{S(m)}.$$

Let $u \in L_{R(m)}$. $h(u) \leq_R m$. (In particular, $h(u) \leq_R m$.)

Write $u = a_0 a_1 a_2 \dots$

Let v be a minimal prefix of u

s.t. $h(v) \leq_R m$.

• $v \neq \epsilon$ since $h(\epsilon) = 1$ and $1 \not\leq_R m$.

• Write $v = w \cdot a$ for $w \in \Sigma^*$ and $a \in \Sigma$.

By minimality of v , $h(w) \not\leq_R m$.

Claim. $h(w) >_g m$.

Proof. Since w is a prefix of u ,

$m \leq_R h(u) \leq_R h(w)$. Thus, $m \leq_R h(w)$.

By earlier, $h(w) \not\leq_R m$.

Thus, $m \not\leq_R h(w)$. That is, $m <_R h(w)$.

$m \leq_R h(w) \Rightarrow n \leq_g h(w)$.

Now, if $n \not>_g h(w)$, then $n \leq h(w)$. But

$m > h(w)$ and $m \leq_R h(w) \Rightarrow m \not\leq_R h(w)$. $\rightarrow \leftarrow$

Thus, $m <_g h(w)$.

□

Claim. $L_{R(m)} = L_{S(m)} \cap \left(\bigcup_{\substack{m' >_g m \\ n, m' \leq_R m}} L_n \cdot \sum_{m'} \cdot \Sigma^* \right)$

$$\sum_{m'} = \{ a \in \Sigma : h(a) = m' \}.$$

Proof let $u \in L_{R(m)}$. $h(u) \leq m \Rightarrow h(u) \leq m \Rightarrow u \in L_{J(m)}$.

Let v be a min'l prefix of u s.t. $h(v) \leq m$.

Write $v = wa$ for $w \in \Sigma^*$, $a \in \Sigma$. $[v \neq \epsilon]$

Then, $n := h(w)$, $m' = h(a)$ gives $h(v) = n \cdot m' \leq m$. \square

Step 3 follows similarly. So do steps 4 and 5 and we are done. \square

Lecture 26 (25-03-2021)

25 March 2021 11:34

Thm Let L be regular. TFAE:

- (i) L is recognised by a ^{finite} aperiodic monoid.
- (ii) L is SF.
- (iii) L is FO-definable.

(i) \Rightarrow (ii) done.

(i) \Rightarrow (iii) similar we do it now:

(other implications simpler.)
in tutorial.

Proof. ① $h^{-1}(1)$ is FO-definable.

$$h^{-1}(1) = L_{\varphi_1} \text{ where } \varphi_1 = \forall x \left(\bigvee_{h(a)=1} a(x) \right).$$

② $\vdash_m : [\forall n \quad n >_J m, h^{-1}(n) \text{ is FO-D} \Rightarrow h^{-1}(m) \text{ is FO-D}]$.

Fix $m \neq 1$. Assume $h^{-1}(n)$ is FO-D $\forall n >_J m$.

Step 1. $\varphi_{J(m)}$

$$\varphi_{\neq_J^m} = \exists x \cdot \left(\bigvee_{\substack{h(a) \neq_J^m \\ a, b, n >_J m}} a(x) \wedge b(y) \wedge \begin{array}{l} \text{the word} \\ a \text{ and } b \text{ in } \\ y \models \varphi_n \end{array} \right)$$

$$\bigvee \exists x \exists y \bigvee \begin{array}{l} ((x < y) \wedge a(x) \wedge b(y) \wedge \\ a, b, n >_J m \\ h(a) \neq h(b)) \neq_J^m \end{array}$$

relativisation

Given sentence φ_n , can create $\hat{\varphi}_n(x, y) \equiv$ the word in (x, y) satisfies φ_n

$$\varphi_{J(m)} = \neg \varphi_{\neq_J^m} \wedge \bigvee_{n >_J m} \left(\bigvee \varphi_n \right).$$

Step 2.

$\varphi_{R(m)}$.

w s.t. $h(w) \in R_m$. Then, $h(w) \in T_m$

$w = a_0 a_1 a_2 a_3 \dots a_k$

$h(a_0 a_1 \dots a_k) \leq_R h(a_0 \dots a_{k-1}) \leq_R \dots \leq_R h(a_0) \leq_R 1$.

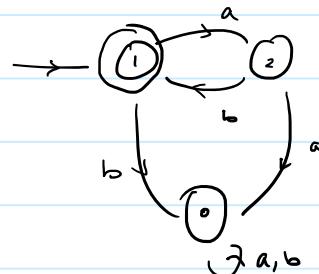

$$\varphi_{R(m)} \equiv \varphi_{T_m} \wedge \left(\exists x \cdot \bigvee_{\substack{n \geq m \\ n \cdot h(a) \in T_m}} \varphi_n \Big|_{(-, x)} \wedge a(x) \right)$$

\downarrow relative formula to the prefix

Step 3. $\varphi_{L(m)} \checkmark$

Step 4. $\varphi_m \equiv \varphi_{R(m)} \wedge \varphi_{L(m)} \checkmark$

Example. $L = (ab)^*$

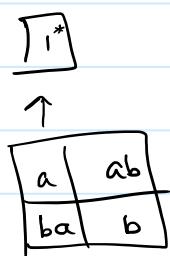

1	1	2
a	2	0
b	0	1
ab	1	0
ba	0	2
aba	2	0

$$M = \{1, a, b, ab, ba, 0\}$$

$$a^2 = b^2 = 0$$

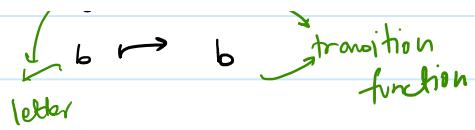

$$aba = a, bab = b$$

$$h: \Sigma^* \rightarrow M$$

$$\begin{array}{ccc} a & \mapsto & a \\ b & \mapsto & b \end{array}$$

transition function

$$h^*(1) = \{ \varepsilon \} \leftrightarrow \exists x \cdot (x = x)$$

Lecture 27 (30-03-2021)

30 March 2021 10:41

Have:

\mathcal{X} -trivial \Leftrightarrow Fo -definable

Comm. + idem. \Leftrightarrow $Fo[1]$ -definable

\mathcal{T} -trivial \Leftrightarrow $B[\Sigma^*]$ -definable

Σ^* - \exists^* sentence and boolean connectives

$\hookrightarrow \exists x_1 \exists x_2 \dots \exists x_k \underbrace{\varphi(x_1, \dots, x_k)}_{\text{quantifier free}}$

$\Pi^* - \forall^*$ sentence

Example. $B[\Sigma^*]$ sentence: $\forall x \forall y (x < y) \wedge a(x) \wedge b(y)$

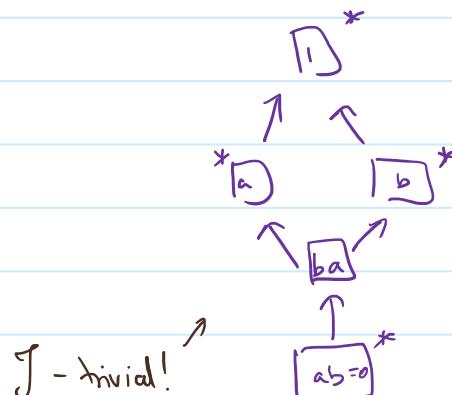

Defn. $u = a_1 \dots a_k \in \Sigma^*$ is a subword of $v \in \Sigma^*$ if
 $\exists v_0, \dots, v_k \in \Sigma^*$ s.t.

$$v = v_0 a_1 v_1 a_2 \dots v_{k-1} a_k v_k.$$

Thus, the language above is the set of those words which have "ab" as a subword.

Ex. $M = \{l, a, b, ab, ba\}$

$$a^2 = a, \quad b^2 = b, \quad aba = ab \\ bab = ab$$

Defn.

Combinatorial congruence

$$u, v \in \Sigma^*, \quad n \geq 0 \quad \text{a parameter}$$

$u \sim_n v$ iff u and v have same subwords of length $\leq n$

Example. $u \sim_1 v \Leftrightarrow u$ and v have the same set of letters
 $c(u) :=$ set of letters occurring in u

$$u \sim_1 v \Leftrightarrow c(u) = c(v)$$

$$ab \sim_1 ba \quad \text{but} \quad ab \not\sim_2 ba$$

$$ab \not\sim_2 aba$$

Lemma: $u \sim_n v$ is a congruence on Σ^* of finite index.

Proof. let $x, y \in \Sigma^*$.

$$\text{Is: } u \sim_n y \Rightarrow xuy \sim_n xy.$$

let w be a subword of xuy s.t. $l(w) \leq n$.

$$\text{Write } w = w_0 w' w_1.$$

embeds in x in u in y

$$\text{But } l(w') \leq l(w) \leq n. \text{ Thus, } u \sim_n v \Rightarrow w' \hookrightarrow v$$

$$\therefore w \hookrightarrow xy.$$

By symmetry, we get $xuy \sim_n xy$.

Finite index: There are only finitely many words of length $\leq n$. The eq. classes is parameterised (naturally) by sets of these words. \square

Lemma. Let $u, v \in \Sigma^*$, $a \in \Sigma$, $n \geq 1$.

If $uav \sim_{2n-1} uv$, then either $ua \sim_n u$ or $av \sim_n v$.

Proof. Suppose not. That is, $ua \not\sim_n u$ and $av \not\sim_n v$.

↓

$\exists x \subset ua$ s.t. $|x| \leq n$ and $x \not\leftrightarrow u$.

(Every subword of u is indeed that of u . Thus, this is the only possibility for x .)

Moreover, x must end in a . $x = x'a$, $|x'| \leq n-1$.

1st $\exists y \subset av$, $|y| \leq n$, $y \not\leftrightarrow v$.

Again, y begins with a . $y = ay'$, $|y'| \leq n-1$

Now, the word $w = x'a y' \rightarrow uaw$ but
 $w \not\leftrightarrow uv$. However, $|w| \leq 2n-1$. ↗

Propⁿ. Let $u, v \in \Sigma^*$ and $n > 0$.

Then, $u \sim_n vu \Leftrightarrow \exists u_1, \dots, u_n \in \Sigma^*$ s.t.

$u = u_1 \dots u_n$ and

$c(v) \subseteq c(u_1) \subseteq \dots \subseteq c(u_n)$.

(Here, we get $c(u_n) = c(u) = c(vu)$.)

Proof If $u = \epsilon$, then it's true. ($v \sim_n \epsilon \Leftrightarrow v = \epsilon$)

(\Rightarrow) By induction on n .

$n=1$. $u \sim_1 vu \Rightarrow c(u) = c(vu) \Rightarrow c(v) \subseteq c(u)$.

Choose $u_1 = u$.

Assume true for $\leq n$.

Suppose $u \sim_{n+1} vu$.

Suppose $u \sim_{n+1} vu$.

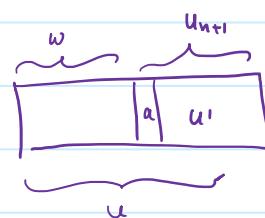

Thus, $c(u) = c(vu)$.

Let $u_{n+1} :=$ shortest suffix of u having the same context as u .

$u_{n+1} \neq \epsilon$. Write $u_{n+1} = a \cdot u'$.

Note that choice of $u_{n+1} \Rightarrow a \notin c(u)$.

Let $w \in \Sigma^*$ be s.t $u = wu_{n+1}$.

Claim. $w \sim_n vw$.

Proof. Let x be a subword of vw of length $\leq n$.

Then, $xa \hookrightarrow vu$ of length $n+1$.

Thus, $xa \hookrightarrow u$.

But $a \notin u'$. Thus, $xa \hookrightarrow wa$.

$\Rightarrow x \hookrightarrow w$. □

By induction, factor w and get it for u . □

(\Leftarrow) Induction on n . $n=1$ is easy.

Assume true $\leq n$.

Given: u, vu s.t. $u = u_1 \cdots u_{n+1}$ with
 $c(v) \subseteq c(u_1) \subseteq \cdots \subseteq c(u_{n+1})$.

To show: $u \sim_{n+1} vu$.

[Assume $u \neq \epsilon$.]

$u_{n+1} \neq \epsilon$ since $u \neq \epsilon$.

let $w = u_1 \cdots u_n$.

By induction, $w \sim_n vw$.

Claim. Every subword of vu of length $\leq n+1$ is also a subword of u .

Let $x \hookrightarrow vu$ with $|x| \leq n+1$.

Example $f = a^3 b^3 a^3 b^3, g = a^2 b^4 a^4 b^2$

Check: $f \sim_4 g$ (Except for baba, all other words of length ≤ 4 can be embedded in both)

$$f \sqcap g = a^2$$

$$\begin{array}{l} f = a^2 \boxed{a} b^3 a^3 b^3 \\ g = a^2 \boxed{b} b^3 a^4 b^2 \end{array}$$

$$\begin{array}{l} g' = a^2 a b b^3 a^4 b^2 = a^3 b^4 a^4 b^2 \\ f' = a^2 b a b^3 a^3 b^3 \end{array}$$

$$f \sim_4 g' \quad \text{or} \quad g \sim_4 f'.$$

(By general theorem)

$$\text{baba} \hookrightarrow f' \quad \text{and} \quad \text{baba} \hookleftarrow g'$$

Thus, $f \sim_4 g'$

Thm Let $L \subseteq \Sigma^*$ TFAE

- (i) L is recognised by a \mathcal{T} -trivial monoid
- (ii) L is a union of \sim_n -classes for some n [Piecewise-testable language]
- (iii) L is definable in the fragment $\mathbb{B}(\Sigma')$

boolean combinations of
 $\exists x_1. \exists x_k. \varphi(x_1, \dots, x_k)$
 quantifier free

Proof (ii) \Rightarrow (i)

• L is a union of \sim_n -classes
 $\rightarrow \Sigma^*/\sim_n$ is a finite monoid
 thus, L can be recognised by $\varphi : \Sigma^* \rightarrow \Sigma^*/\sim_n$
 $\omega \mapsto [\omega]$

We have "shown" that Σ^*/\sim_n is \mathcal{T} -trivial

(ii) \Rightarrow (iii)

Fix a \sim_n -class and a word $w = a_1 \dots a_k$ of length $k \leq n$.

$$\varphi_w = \exists x_1 \dots \exists x_k \left(\left[\bigwedge_{i < j} x_i < x_j \right] \wedge \left[\bigwedge_i a_i(x_i) \right] \right)$$

Note $u \models \varphi_w \Leftrightarrow w \hookrightarrow u$

Now take $\bigwedge \varphi_w$ over all w with $|w| \leq n$

(ii) \Rightarrow (iii)

[Observe] Let $\varphi_\alpha = \exists x_1 \dots \exists x_k \varphi(\quad)$

\uparrow
q-free

Suppose $u \sim_n v$ Then $u \models \varphi_\alpha \Leftrightarrow v \models \varphi_\alpha$.

Lecture 30 (06-04-2021)

06 April 2021 10:28

(i) \Rightarrow (ii) L is recognised by a morphism $\varphi: \Sigma^* \rightarrow M$ where M is a finite T -trivial monad

Let n be the maximum length of a T -chain in M
(Can take $n = |M|$ as well)

Claim L is a union of \sim_{n-1} -classes

Proof What we show is that

$$f \sim_{n-1} g \Rightarrow \varphi(f) = \varphi(g)$$

(This, in turn, proves the claim)

To this end, let $f, g \in \Sigma^*$ be s.t. $f \sim_{n-1} g$

We may assume that $f \hookrightarrow g$

$$\left[\exists h \in \Sigma^* \text{ s.t. } f \hookrightarrow h, g \hookrightarrow h \text{ and } f \sim_{n-1} h \right]$$

In fact, we can even assume that $f = uv$ and $g = uav$

$\left[\text{Given } f \hookrightarrow g, \text{ we can find } g' \text{ s.t. } f \hookrightarrow g' \hookrightarrow g \text{ and} \right]$

$$uv \sim_{n-1} uav \Rightarrow u \sim_n ua \text{ or } v \sim_n av. \quad \begin{matrix} (\text{Recall from}) \\ \text{earlier} \end{matrix}$$

- Suppose $v \sim_n av$ (Then we show $\varphi(v) = \varphi(av)$)

$$\begin{aligned} \varphi(f) &= \varphi(uv) = \varphi(u)\varphi(v) \\ &= \varphi(u)\varphi(av) = \varphi(g) \end{aligned}$$

\rightarrow By the context lemma, $v = v_1 \dots v_n$ with

$$\{a\} \subseteq c(v_1) \subseteq \dots \subseteq c(v_n)$$

$$\varphi(v_1 \dots v_n) \leq_T \dots \leq_T \varphi(v_{n-1} v_n) \leq_T \varphi(v_n) \leq_T 1$$

$$\downarrow \qquad \qquad \qquad \downarrow \qquad \qquad \qquad \downarrow \qquad \qquad \qquad \downarrow$$

$$1 \qquad \qquad \qquad n-1 \qquad \qquad \qquad n \qquad \qquad \qquad n+1$$

By defⁿ of n , $\exists i \quad \varphi(v_1 \dots v_n) \not\leq \varphi(v_{i+1} \dots v_n)$

(not all can be strict \leq_g)

But M is T -trivial Thus, $\varphi(v_1, v_{l+1}, \dots, v_n) = \varphi(v_{l+1} \cdot \dots \cdot v_n) = s$

Subclaim: $\forall b \in c(v_i) : \varphi(b) s = s$ (Same v as above)

Proof: $b \in c(v_i), v_i = v_i' b v_i''$

$$s = \varphi(v_i, v_{l+1}, \dots, v_n) \leq_g \varphi(bv_i'', v_{l+1}, \dots, v_n) \leq_g \varphi(v_i'', v_{l+1}, \dots, v_n) \leq_g \varphi(v_{l+1} \cdot \dots \cdot v_n) = s$$

Again, by T -triviality, all the elements above are s

$$\text{Thus, } s = \varphi(bv_i'', v_{l+1}, \dots, v_n)$$

$$= \varphi(b) \varphi(v_i'', v_{l+1}, \dots, v_n) = \varphi(b) s$$

□

$$\text{Thus, } \varphi(av) = \varphi(av_1, \dots, v_{l-1}) \varphi(v_l, v_{l+1}, \dots, v_n)$$

$$= \varphi(av_1, \dots, v_{l-1}) s$$

$$\hookrightarrow c(av_1, \dots, v_{l-1}) \subseteq c(v_1)$$

$$= s$$

$$\text{Similarly, } \varphi(v) = s$$

This proves $\varphi(u) = \varphi(av)$, as desired

(The case $u \sim_n ua$ is similar)

Thus, we are done

□

Simon's Theorem $L \subseteq \Sigma^*$ TFAE

(1) L is piecewise-testable.

(2) The syntactic monad of L is T -trivial

(3) L is recognised by a finite T -trivial monad.

Lecture 31 (08-04-2021)

08 April 2021 11:37

Ordered semigroups and ordered monoids

Defn: An ordered semigroup is a semigroup (S, \cdot) along with a partial order on S which is compatible with the semigroup structure.

That is,

$$\forall s_1, s_2 \in S \text{ and } \forall p, q \in S' \quad s_1 \leq s_2 \Rightarrow ps_1q \leq ps_2q$$

An ordered monoid (M, \cdot, \leq) is an ordered semigroup where (M, \cdot) is a monoid

- Example
- (1) $(\mathbb{N}, +, \leq)$ $\xrightarrow{\text{usual } \leq}$ ordered semigroup (In fact \leq is a total order)
 - (2) (\mathbb{N}, \max, \leq) \rightarrow ordered semigroup

$$(3) U_1 = \{1, 0\}$$

$$\begin{array}{c} 1 & 0 \\ \hline 1 & | & 0 \\ 0 & | & 0 & 0 \end{array} \quad \begin{array}{l} U_1^+ \cdot 0 < 1 \\ U_1^- \cdot 1 < 0 \\ U_1^= \cdot \leq \equiv = \end{array} \quad \left. \begin{array}{l} \\ \\ \end{array} \right\} \text{ordered monoid}$$

(4) In general, if (S, \cdot) is a semigroup/monoid, then (S, \cdot, \leq) is an ordered semigroup/monoid

Thus, can interpret ordinary semigroup/monoid as an ordered one.

(5) (Σ^*, \cdot, \leq) is an ordered monoid

Defn: A morphism φ from (S, \cdot, \leq) to (T, \cdot, \leq) is a map $\varphi: S \rightarrow T$, (1) φ is a semigroup/monoid morphism,
(2) $s_1 \leq s_2 \Rightarrow \varphi(s_1) \leq \varphi(s_2) \quad \forall s_1, s_2 \in S$

Example: Suppose (S, \cdot, \leq) is an ordered semigroup/monoid.

$\text{Id}_S : S \rightarrow S$ is an ordered semigroup/morphism from (S, \cdot, \leq) to (S, \cdot, \leq) .

Product of ordered semigroups

(S_1, \leq) and (S_2, \leq) be ordered semigroups. $(S_1 \times S_2, \leq')$ is also an ordered semigroup with order $(s_1, s_2) \leq' (s'_1, s'_2) \iff (s_1 \leq s'_1) \text{ and } (s_2 \leq s'_2)$

Order congruence on ordered semigroups

$(S, \cdot, \leq) \rightarrow \text{ordered semigroup}$

Defⁿ A congruence on (S, \cdot, \leq) is a pre-order (reflexive + transitive) \leq' on S s.t.

$$(1) \quad x \leq y \Rightarrow x \leq' y \quad \forall x, y \in S$$

$$(2) \quad x \leq' y \Rightarrow axb \leq' ayb \quad \forall x, y \in S, \forall a, b \in S'$$

Quotienting mod this congruence.

Let \leq' be a congruence on (S, \cdot, \leq)

Let \approx be the associated eq. relⁿ to \leq'

$$(x \approx y \Leftrightarrow x \leq' y \text{ and } y \leq' x)$$

Easy to see that \approx is a congruence on the semigroup (S, \cdot)

[Recall that this meant: $x \approx y \Rightarrow axb \approx ayb \quad \forall x, y \in S \quad \forall a, b \in S'$]

Thus, we get the semigroup S/\approx

[Recall the operation $[x]_{\approx} [y]_{\approx} = [xy]_{\approx}$ made it a semigroup]

On thus, we have the relation \leq' given as

$$[x]_{\approx} \leq' [y]_{\approx} \text{ iff } x \leq' y$$

Well-defined? $x \approx x'$ and $y \approx y'$ and $x \leq y \Rightarrow x' \leq x \leq y \leq y'$
 \Downarrow
 $x' \leq y'$ ✓

Moreover \leq is a partial order

In fact, \leq is compatible with .

$$[s_1]_{\approx} \leq [s_2]_{\approx} \Rightarrow [a]_{\approx} [s_1]_{\approx} [b]_{\approx} \leq [a]_{\approx} [s_2]_{\approx} [b]_{\approx}$$

$$[as, b]_{\approx} \quad [as_2 b]_{\approx}$$

At times, we denote S/\approx by S/\leq instead

$$\pi: S \rightarrow S/\approx$$

$$x \mapsto [x]_{\approx} = \pi(x)$$

π is a surjective morphism from (S, \cdot, \leq) to $(S/\approx, \cdot, \leq)$

$(\Sigma^*, ;, =) \rightarrow$ ordered monoid

$L \subseteq \Sigma^*$, \leq_L — a congruence on $(\Sigma^*, =)$
 (will define next class)

Then, we can get a (finite) ordered monoid Σ^*/\leq_L (if L is regular)
